

# Futu RaM

Future availability  
of secondary  
raw materials

## Work Package 2

Future recovery of secondary raw materials

Scenario Development

DRAFT REPORT

VERSION: 2.0

Stewart Charles McDowall  
s.c.mcdowall@cml.leidenuniv.nl

October 12, 2023

## THIS IS A DRAFT REPORT

please submit comments and corrections to [s.c.mcdowall@cml.leidenuniv.nl](mailto:s.c.mcdowall@cml.leidenuniv.nl) or directly:

- In a CSV file with the format: 'line number, comment, name, reference' (if reference is applicable, please provide the DOI or BibTeX).
- FutuRaM members can do this directly via [this link](#).
- Or directly as a pull request to the  $\text{\LaTeX}$  source files on the [WP2 GitHub repository](#).

## TO DO

- Add more references, especially for the targets, regulations, and projections.
- Waste stream groups to re-check the sections related to their waste streams.
- Discuss main points raised by reviewers:
  - How to transfer general targets to individual waste streams?
    - \* We would need constraints for each of the flows and processes in each WS to backcast this.
  - Consideration of possible resource constraints in the scenarios.
    - \* We suggest to cover this in sensitivity analysis and optimisation playground.
  - E-mobility.
    - \* Do we hold it level across the scenarios?
    - \* In Germany, the Autolobby und Deutschland GmBh. have killed the ICE ban...
  - Economic Considerations.
    - \* Addressing the fact that industrial ecology scenarios often exclude or have a limited view of economic factors.
  - Geopolitical Considerations.
    - \* How geopolitical changes and directions are being factored into the scenarios.
  - Names for EU Member States and Other Countries.

- \* Clarifying which countries are included in the study and the terms used.
- Scenario Relation with UNFC.
  - \* Addressing the relevance of the scenarios with the United Nations Framework Classification (UNFC).

# 1 I. Preface

2 The **FutuRaM project** seeks to quantify the current and future availability of secondary raw  
3 materials (SRM) with a focus on critical raw materials (CRMs) [1] for six waste streams. The  
4 waste streams are:

- 5 • waste electrical and electronic equipment (WEEE)
- 6 • waste batteries (BAT)
- 7 • end-of-life vehicles (ELV)
- 8 • mining waste (MIN)
- 9 • slags and ashes (SLASH)
- 10 • construction and demolition waste (CDW)

11 Work package 2 (WP2) is conducting foresight studies for materials critical to the EU econ-  
12 omy, or materials that have significant impacts on EU sustainability because of their large  
13 volumes [1, 2, 3, 4]. WP2 is developing a set of coherent scenarios for material use and  
14 waste/recovery over time in various sectors in the EU. This report describes the three scenarios  
15 and the process by which they were developed. The scenarios are:

- 16 • Business as usual (BAU)
- 17 • Recovery (REC)
- 18 • Circularity (CIR)

## 19 II. Executive Summary

20 This report presents the first phase of the scenario development process — the storyline  
21 narrative phase. Three distinct future scenarios have been drafted up to the year 2050, Business  
22 as usual, Recovery and Circularity. The scenarios are designed to be internally consistent and to  
23 provide an overview of the potential future landscape of waste management and SRM recovery  
24 within the EU. The scenario development process employs a methodology that integrates both  
25 forecasting and backcasting techniques to construct a comprehensive, future-facing knowledge  
26 base that can aid fact-based decision-making [5, 6, 7, 8, 9, 10].

### 27 **Scenario 1: Business as Usual (BAU)**

28 The BAU scenario extends the current situation into the future with limited deviation from  
29 existing patterns. Utilising forecasting techniques, it assesses a potential future where are minor  
30 advancements in resource efficiency, recovery technology, and the energy transition, but in  
31 which primary extraction of raw materials remains the dominant practice.

### 32 **Scenario 2: Recovery (REC)**

33 The Recovery scenario envisions a future that employs sophisticated technology to dramatically  
34 enhance SRM recovery from waste streams. It presents a future where the EU successfully  
35 meets its recycling and recovery targets through an effective waste management system and  
36 circular design principles [11, 12]. The scenario envisions an increased recovery rate of SRMs,  
37 extensive use of digitalisation and automation in recycling processes, and the implementation  
38 of new (or enforcement of existing) waste regulations in alignment with EU targets.

### 39 **Scenario 3: Circularity (CIR)**

40 The Circularity scenario encapsulates the fullest possible realisation of a circular economy,  
41 extending beyond end-of-life recovery of materials to minimising waste at all stages of produc-  
42 tion and consumption. It envisions a future where the EU's targets for recycling, recovery, and  
43 circularity are met through extensive stakeholder collaboration, the emergence of new business  
44 models, and increased use of renewable energy and circular economy technologies [13, 14, 15].

45 In subsequent phases of the scenario development process, future product composition

46 and recovery technology will be examined, scenario elements will be quantified, and all scenario  
47 data will be integrated and coupled with the quantitative models for waste generation and  
48 SRM recovery.

49 Through the development of these scenarios, the FutuRaM project aims to provide a nu-  
50 anced understanding of the potential future waste management and resource recovery land-  
51 scape within the EU. This approach offers insights into key drivers, uncertainties, and the  
52 potential impacts of policy interventions and technological advancements. By aligning SRM  
53 recovery projects more closely with the United Nations Framework Classification for Resources  
54 (UNFC) [16], the project aims to enable the commercial exploitation of SRMs and CRMs by  
55 manufacturers, recyclers, and investors. Ultimately, the comprehensive knowledge base devel-  
56 oped through this process is designed to support and inform the decision-making processes of  
57 policymakers and governmental authorities.

## 119 VI. Summary of scenario storylines

### 120 Scenario I: Business as usual (BAU)

121 See section 2.1 for the full scenario description and waste-stream-specific scenario impact  
122 narratives.

123 This scenario envisions the future based on the current situation, extending to 2050 with  
124 very little deviation from present consumption patterns and without substantial development  
125 of the secondary raw material (SRM) recovery system. While there may be advances in some  
126 areas such as resource efficiency, recovery technology, and the energy transition, substantial  
127 modifications remain hindered by economic, social, and political constraints. The extraction of  
128 primary raw materials continues to be the predominant source utilised to satisfy EU's growing  
129 SRM demand.

130 In the Business as usual (linear economy) scenario, the following are key characteristics:

- 131 • A forecasting model is used to predict the future based on the current situation and the  
132 development of existing trends.
- 133 • EU targets including those for ecodesign, recycling and recovery are not met, and the  
134 current linear model largely persists.
- 135 • Material demand remains coupled to GDP growth, perpetuating a trend of increasing  
136 consumption.
- 137 • Primary mining and extraction persist as the leading sources of raw materials, underlining  
138 the dependency on traditional extraction methods.
- 139 • Recycling and recovery rates continue to lag, leading to increased production of SRM  
140 containing waste that signals missed opportunities for resource reuse.
- 141 • The EU's dependency on imports of SRMs escalates, heightening the risk of supply  
142 disruptions [17].

- 143 • Investment in new SRM recovery technologies remains minimal, stifling innovation and  
144 advancements in this field.
- 145 • The industrial focus remains on cost-effective material production and use, disregarding  
146 the long-term sustainability aspect.
- 147 • Material scarcity and price fluctuations pose potential risks to the EU industry, highlighting  
148 the vulnerability of this business model [18].
- 149 • Without any significant updates to environmental regulations, the negative impacts on  
150 ecosystems and biodiversity intensify.
- 151 • Mining activity in the EU remains limited and concentrated in only a few member  
152 states. Current exploration projects (e.g., for Lithium in PT, FR, UK and rare earths in  
153 SE) are not realised.
- 154 • The transitions to renewable energy and e-mobility continue at their current pace.

## 155 **Scenario II: Recovery**

156 See section 2.2 for the full scenario description and the waste-stream-specific scenario impact  
157 narratives.

158 In the recovery scenario, the central emphasis is on harnessing sophisticated technologies  
159 to salvage SRMs from waste streams at the end of their lifecycle. While there are noticeable  
160 strides towards the incorporation of 'circular design' principles and re-X strategies (which focus  
161 on reducing, reusing, recycling, repairing, and refurbishing), material demand increases similarly  
162 to the BAU scenario. This is, however, mitigated to some extent by the implementation of a  
163 comprehensive material recovery system.

164 Key characteristics of this technology promoted recovery scenario include:

- 165 • This scenario uses a combination of the forecasting and backcasting methods to envision  
166 the future.

- 167 • The backcasting method is used for scenario factors that are covered by governmental  
168 targets, starting with the desired outcome and working backwards to the present.
- 169 • The forecasting method is used for scenario factors that are not covered by governmental  
170 targets, starting with the current situation and extending to the future.
- 171 • EU targets for recycling and recovery are met, due to the EU's waste management system  
172 becoming more expansive, efficient and effective.
- 173 • Technological innovation drives increased recovery rates of SRMs, enabling the more  
174 efficient use of waste.
- 175 • Digitalisation and automation are more extensively used in recycling processes, leading  
176 to enhanced productivity and efficiency.
- 177 • Business models like leasing and take-back schemes emerge, altering traditional con-  
178 sumption patterns (here, the focus is on take-back for recycling).
- 179 • Ecodesign mandates are implemented, again, here, with a focus on end-of-life recovery.
- 180 • There is greater exploration and exploitation of alternative sources such as urban mining,  
181 waste streams, and tailings, presenting novel opportunities for resource acquisition.
- 182 • New waste regulations and guidelines for SRM recovery are implemented, enforcing  
183 better management and extraction of SRMs.
- 184 • Investment in research and development for SRM recovery technologies experiences an  
185 upswing, promoting continuous innovation in this field.
- 186 • Closer collaboration and information sharing between industry and government insti-  
187 tutions (e.g., waste tracking and digital product passports) streamline processes and  
188 expedite decision-making.
- 189 • New jobs are created in the recycling and recovery sector, offering economic benefits  
190 and improving overall employment rates.
- 191 • SRM production and use become more efficient and cost-effective, fostering economic  
192 sustainability.

### 193 **Scenario III: Circularity**

194 See section 2.3 for the full scenario description and the waste-stream-specific scenario impact  
195 narratives.

196 In this scenario, we move in the direction of the maximum achievable state of material  
197 efficiency as government policy, private innovation and social changes are rapidly driving the  
198 transition toward a circular economy. The emphasis here rests heavily on re-X strategies that  
199 are implemented in the design phase of products (e.g., repairability and re-manufacturability)  
200 and that are actualised by changes in consumer behaviour (e.g reduction, refusal, engagement  
201 in the 'sharing-economy' and curtailment of the 'throw-away' mindset). Further, being enabled  
202 by the widespread adoption of 'circular design' principles and improvements in information  
203 transparency (e.g., waste tracking and digital product passports) the system for the treatment  
204 of post-consumer waste can divert a significant amount of their inflows (to, for example, re-  
205 use and re-manufacture) with the residual fraction being readily segregated into purer, more  
206 efficiently recoverable, material streams. This scenario envisions a future where government  
207 policies are in synergy with private sector innovation and societal changes, driving a wholesale  
208 transition towards a circular economy. Unlike the recovery scenario, where the focus is on  
209 the end-of-life recovery of materials, this scenario emphasises minimising waste at all stages,  
210 starting from the design phase itself.

211 **The circular economy scenario is characterised by the following:**

- 212 • This scenario uses a combination of the forecasting and backcasting methods to envision  
213 the future.
- 214 • The backcasting method is used for scenario factors that are covered by governmental  
215 targets, starting with the desired outcome and working backwards to the present.
- 216 • The forecasting method is used for scenario factors that are not covered by governmental  
217 targets, starting with the current situation and extending to the future.
- 218 • EU targets for recycling and recovery are met, as are those for circularity, due advances  
219 in waste management, ecodesign and re-X strategies.

- 220 • A circular economy is implemented, prioritising waste reduction, resource efficiency, and  
221 a shift from the 'take-make-dispose' model.
- 222 • A notable increase in SRM recycling and recovery rates, indicating an efficient use of  
223 resources.
- 224 • A larger emphasis on designing products for reuse and recycling, making waste a valuable  
225 resource rather than a problem.
- 226 • More extensive use of renewable energy and clean technologies in SRM production and  
227 use, supporting a low-carbon economy.
- 228 • Collaboration between stakeholders, including industry, government, and consumers,  
229 improves, enhancing the implementation of circular practices.
- 230 • New business models like leasing and take-back schemes emerge, altering traditional  
231 consumption patterns [19].
- 232 • Digitalisation and data use are heightened to improve efficiency and traceability, aiding  
233 in effective resource management.
- 234 • Investment in research and development for circular economy technologies increases,  
235 driving innovation and adoption.
- 236 • Awareness and education around sustainable consumption and production practices are  
237 amplified, leading to behavioural changes in society.
- 238 • Reliance on imports decreases, suggesting greater self-sufficiency and sustainability.
- 239 • The creation of new jobs within the recycling, recovery and re-X sectors boosts the  
240 economy and alleviates social inequality.
- 241 • Stricter waste regulations and product design guidelines are introduced, accelerating the  
242 transition towards circularity.

## VII. Acronyms

Table 0.1: List of acronyms

Acronym	Definition
AI	Artificial Intelligence
BAU	Business as Usual
BATT	Waste Batteries
CDW	Construction and Demolition Waste
CE	Circular Economy
CRM	Critical Raw Material
EEE	Electrical and Electronic Equipment
ELV	End-of-Life Vehicles
EoL	End-of-Life
EoU	End-of-Use
EoW	End-of-Waste
EU	European Union
EPR	Extended Producer Responsibility
GDP	Gross Domestic Product
LCA	Life Cycle Assessment
MIN	Mining Waste
R&D	Research and Development
REACH	Registration, Evaluation, Authorization, and Restriction of Chemicals
SLASH	Slags and Ashes
S-LCA	Social Life Cycle Assessment
SRM	Secondary Raw Material
UNFC	United Nations Framework Classification for Resources
WEEE	Waste Electrical and Electronic Equipment
WFD	Waste Framework Directive

## 244 VIII. Terminology (abbreviated)

245 The following table provides an abbreviated list of terminology used in this report.

246 See section 5.1 for a complete list.

Table O.2: List of terminology (abbreviated)

Term	Definition
Backcasting	A method for predicting future trends based on a desired future state.
Business-as-usual	A scenario that assumes no significant changes in current trends and policies.
Circular economy	An economic system that prioritises waste reduction and resource efficiency.
Critical Raw Material	A raw material that is economically and strategically important to the EU, but with a high risk of supply disruption.
Forecasting	A method for predicting future trends based on historical data.
Recovery	The process of recovering SRMs from waste streams.
Re-X	A general term for circular strategies such as reuse, repair, refurbishment, remanufacturing and recycling.
Scenario	A plausible and coherent description of how the future may develop based on a set of assumptions.
Secondary Raw Material	A material that has been recovered from waste and can be used as a substitute for a primary raw material.
Storyline	A qualitative description of a scenario, including the key drivers, actors and events.

# IX. Description of FutuRaM work package task 2.1

## Associated milestones

Table O.3: Milestone list

Milestone	Milestone name	WP	Due date	Resp. partner	Means of verification
MS11	Mapping of published scenarios and Story-line/scenario description	2	Dec. 2023	ULEI	Dataset on available scenarios is fed into D1.1 and qualitative descriptions of 3 futures for the six waste streams are circulated

## Associated subtasks

Table O.4: Subtask list

WP	Task	Sub Task	Name	Waste Group	Description of sub-task	Start	End	Contributors	Status
2	2.1	2.1	Scenario mapping	Cross Cutting	Map various studies from the academic, policy, and grey literature for future scenarios and assess the applicability within FutuRaM	M01	M05	WEEE Forum, UNITAR, BRGM, Chalmers, GTK, LMU, RECHARGE, SGU, TUB, Leiden Uni, VITO, Empa, UCL	x
2	2.1	2.2	Scenario methods	Cross Cutting	Compile various methodologies for scenario development and assess their applicability for developing scenarios on material recovery and circular economy for Europe	M02	M05	WEEE Forum, UNITAR, BRGM, Chalmers, GTK, LMU, RECHARGE, SGU, TUB, Leiden Uni, VITO, Empa, UCL	x
2	2.1	2.3	Scenario storylines	Cross Cutting	Flesh out the storylines of the 3 main scenarios	M05	M08	UNITAR, Chalmers, TUB, Leiden Uni	x
2	2.1	2.4	Qualitative scenario development	Cross Cutting	Use the chosen methods and qualitative methods to develop the three main scenarios to be used in FutuRaM (e.g. BAU, increased material recovery, and full circular economy)	M07	M11	UNITAR, Chalmers, SGU, Leiden Uni, VITO, UCL	DRAFTED

## 251 **Chapter 1**

## 252 **Methodology**

## 1.1 The conceptual framework for scenario development

The conceptual framework for scenario development is based on the following principles.

The scenarios should:

- Be based on the best available scientific knowledge and data.
- Provide a coherent and consistent picture of the future.
- Provide decision makers with knowledge related to the possible consequences of their decisions.
- Consider a range of plausible future outcomes, accounting for uncertainties and alternative trajectories.
- Be developed in a participatory and collaborative manner, involving relevant stakeholders and experts.
- Be transparent and well-documented, allowing for replication and further analysis (e.g., publication in peer-reviewed journals and open access repositories)
- Be flexible and adaptable, allowing for updates and adjustments as new information becomes available.
- Consider the interconnections and interactions between different sectors, waste streams, and policy domains.
- Take into account the broader societal, economic, and environmental context in which the waste streams operate.
- Incorporate a long-term perspective, considering the potential impacts and implications over several decades.
- Capture both quantitative and qualitative aspects, integrating data-driven modelling with qualitative narratives and storylines.

- 276 • Be regularly reviewed and updated to reflect evolving knowledge, technological advance-  
277 ments, and policy developments.
- 278 • Be used as a tool for learning and exploration, encouraging dialogue and collaboration  
279 among stakeholders.
- 280 • Inform policy and decision-making processes, providing insights into the potential con-  
281 sequences of different choices and interventions.
- 282 • Be communicated effectively to a wide range of audiences, ensuring accessibility and  
283 clarity of information.
- 284 • Contribute to the advancement of knowledge and understanding in the field of waste  
285 management, resource recovery, and circular economy.

286 By adhering to these principles, the FutuRaM project aims to develop robust, informative,  
287 and policy-relevant scenarios that support sustainable decision-making and contribute to the  
288 transition towards a more circular and resource-efficient economy. The methodology ensures  
289 that the scenarios capture the complexity and interconnectedness of the waste streams, taking  
290 into account, where possible, factors such as legislation, technology, geopolitics, and societal  
291 values. Ultimately, the goal is to provide decision makers with valuable insights and tools to  
292 navigate the challenges and opportunities associated with secondary raw materials in a rapidly  
293 changing world.

## 294 1.2 Scenario storyline development process

295 Building scenarios involves several steps and methodologies, which can vary depending on the  
296 specific context and objectives [5, 6, 7, 8, 20, 21, 22, 23]. The following section provides an  
297 overview of the scenario development process used in FutuRaM. Figure 1.1 provides a visual  
298 representation of the process.

### 299 1.2.1 Step 1: Define the scope and objectives

#### 300 Scope and objectives of the scenario development process

301 The scope and objectives of the scenario development process are defined in the context  
302 of the overall aim, scope, and objectives of the FutuRaM project.

##### 303 Aim:

304 FutuRaM will develop the Secondary Raw Materials knowledge base on the availability  
305 and recoverability of secondary raw materials (SRMs) within the European Union (EU), with  
306 a special focus on critical raw materials (CRMs). The project research will enable fact-based  
307 decision making for the recovery and use of SRMs within and outside the EU, and disseminate  
308 the data generated via an accessible knowledge base developed in the project.

##### 309 Scope:

310 FutuRaM will establish a methodology, reporting structure, and guidance to improve the  
311 raw materials knowledge base up to 2050. FutuRaM will focus on six waste streams: batteries;  
312 electrical and electronic equipment; vehicles; mining; slags and ashes; and construction and  
313 demolition. It will integrate SRM and CRM data to model their current stocks and flows, and  
314 consider economic, technological, geopolitical, regulatory, social and environmental factors  
315 to further develop, demonstrate and align SRM recovery projects with the United Nations  
316 Framework Classification for Resources (UNFC) [16], a tool that enables a better understanding  
317 of the viability of raw material projects. This will enable the commercial exploitation of SRMs  
318 and CRMs by manufacturers, recyclers, and investors, and the knowledge base developed in  
319 the project will support policy makers and governmental authorities.

320 Selected objectives of the FutuRaM project are presented in Table 1.1.

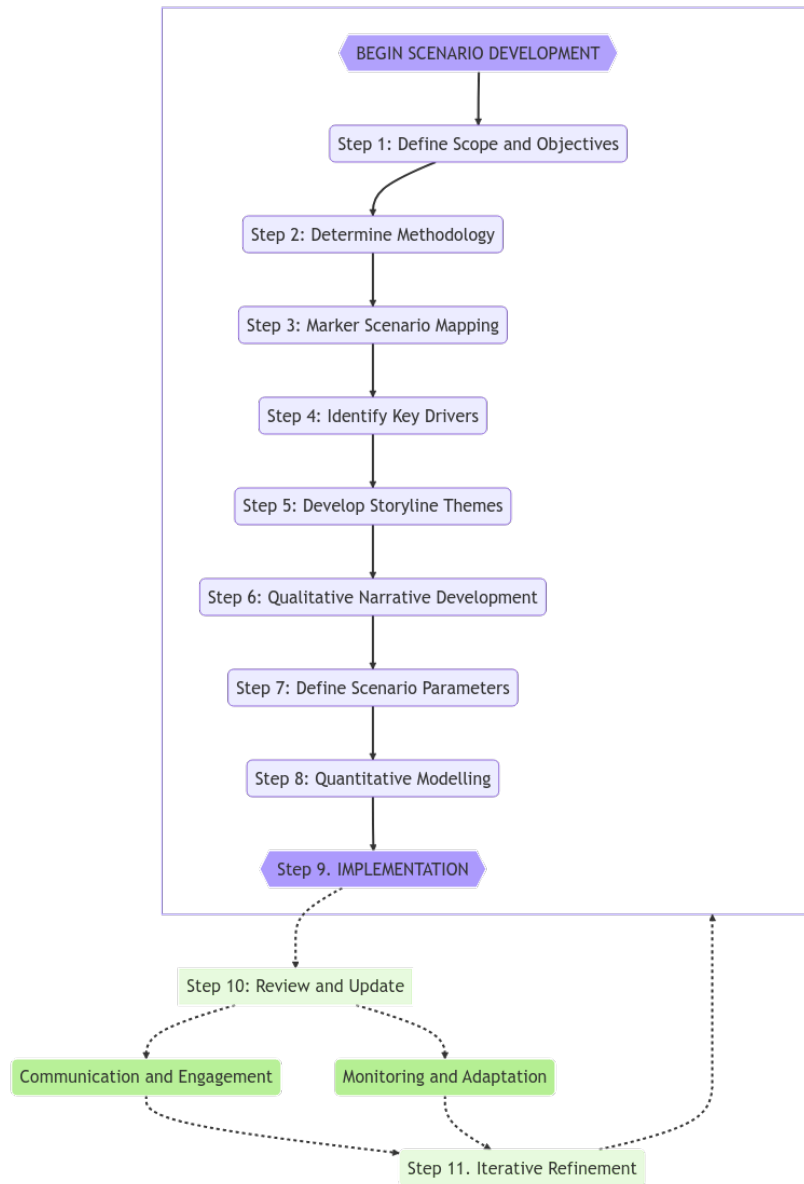

Figure 1.1: Scenario storyline development process

Table 1.1: Selected objectives of FutuRaM

Need	Action
A successful transition to a climate-neutral, circular and digitised EU economy relies heavily on a secure supply of raw materials. In order to strengthen EU autonomy and reduce over-dependency, we must boost domestic sourcing, both for primary and SRMs	FutuRaM will quantify the future availability of SRMs for three future scenarios for the EU material economy, from following current consumption trends, to moderate or rapid transitioning toward a climate-neutral, circular, and digitised EU economy (WP2). The material demand and the SRMs supply for each scenario and raw material imports to evaluate EU material autonomy.
Presently, several socioeconomic scenarios have been developed at national, EU, and/or global scales to assess the energy and mobility transition. While some of these studies have partially included CRMs demand and focused on the potential supply risks for achieving climate targets, these prospective scenarios have not been effectively harmonised across industrial sectors, and generally lack information on SRMs and the recovery industry in general. Transitions toward sustainable societies are likely to involve major changes and increased complexity in the material economy. Further research into current and future SRMs and CRMs present in the urban mine is thus urgent to prepare industry for their eventual recovery. In addition, scenarios that include other Circular goals such as lifetime extension need to be better assessed in terms of material cycles	FutuRaM will develop stock-flow models for six waste streams based on holistic scenarios to map current and future material use in the economy of the EU-27 plus Iceland, Norway, Switzerland and United Kingdom (EU27+4) and quantify their eventual end-of-life fate. FutuRaM will extend existing model approaches by a set of distinct scenarios which cover circular economy (e.g., lifetime extension through repair and remanufacturing), high SRMs recoverability, and business as usual. These scenarios will incorporate emerging recycling technologies in line with stakeholder dialogues that consider normative boundary conditions such as carbon neutrality by 2050.

**Scope definition:**

Given this context, the scope of the scenario development process is to develop a set of plausible scenarios that explore the future of waste management, resource recovery, and circular economy in the EU. The scenarios will be used to identify key drivers and uncertainties that will influence the future of waste management and resource recovery. The scenarios will also be used to evaluate the potential impacts of different policy interventions and technological advancements.

*Thematic scope*

The scenarios will be centered on the six waste streams of FutuRaM: WEEE, ELV, BAT, CDW, MIN, and SLASH. Additionally, consideration will be given to sectors and policy domains that are relevant to these waste streams and the general context of the system. These include manufacturing, energy, transportation, as well as policy related to the environment, the economy, society, technology, and geopolitics.

*Geographic scope*

The scenarios will be developed for the EU-27 plus Iceland, Norway, Switzerland and United Kingdom (EU27+4). The scenarios will consider the current and future waste management practices and resource recovery technologies in these countries. Additionally, the scenarios will consider the current and future policies and targets related to waste management and resource efficiency in these countries. To some extent, the scenarios will also consider the current and future trade relationships between these countries and other countries around the world.

*Temporal scope*

The scenarios will be developed for the time horizon of 2025–2050. This time horizon is aligned with the long term targets of the EU, including the EU Green Deal, the EU Circular Economy Action Plan, and the EU Industrial Strategy. The discrete stages in the forecasts are planned to be: 2025, 2030, 2035, 2040, 2045 and 2050. The temporal resolution of the scenarios will be determined during the quantification phase of the scenario development process. While it is possible to develop scenarios with a high (or even continuous) temporal resolution, that of these scenarios will be determined based on the availability and quality of

349 data. It is important to acknowledge that providing too high a temporal resolution may lead  
350 to a false sense of accuracy and precision. Furthermore, the scenarios will be developed with  
351 the understanding that the further into the future we look, the more uncertain the predictions  
352 become [7].

### 353     **Aims and objectives definition**

354     The specific objectives of the FutuRaM scenario building process are presented in Table 1.2.

Table 1.2: FutuRaM WP2 aims and objectives

Aim	Objective
Quantifying the current and future availability of secondary raw materials (SRM), particularly critical raw materials (CRM), for the identified waste streams from 2025 until 2050	Develop a set of plausible scenarios that encompass these waste stream and provide quantitative estimates of the current and future availability of SRM and CRMs.
Informing private and public sector decision-making processes by assessing the impacts of different legislative and policy strategies related to waste management and resource efficiency	The scenarios will cover a range of such strategies, grouped in coherent sets in each of the three storylines including recycling, reuse, remanufacturing, and landfilling. Integration of the scenario with the system model will allow assessment of the impacts of these strategies on not only the availability of SRM and CRMs, but also on the environment, the economy, and society.

### Consideration of EU legislation and policy targets

The scenarios developed in FutuRaM include the targets that the EU is setting for specific elements/materials/waste streams, following, in particular, the ambitions of the EU Green Deal [24] and the proposed critical raw materials (CRM) legislation [2]. Additionally, the consumer-product-centric waste streams BATT, ELV, and WEEE have specific EU legislation that will be considered in the scenarios.

### General policies and legislation

**The EU Green Deal [24]** is a set of policy initiatives by the European Commission with the overarching aim of making Europe climate neutral in 2050. This policy portfolio is a response to the Paris Agreement and the United Nations Sustainable Development Goals and it covers a wide range of economic sectors with an emphasis on investments toward building up local, 'sustainable' industries. The scope of FutuRaM is aligned with the EU Green Deal's goal of ensuring the sustainable sourcing and use of raw materials, reducing dependency on imports, and promoting resource security. These goals can conflict with each other, however, and the modelling in FutuRaM will explore the trade-offs between them (e.g., optimising local sourcing may result in higher negative externalities).

**The EU Circular Economy Action Plan [13]** is a policy framework developed by the European Commission to promote the circular economy in the European Union. It sets out a comprehensive set of measures and targets to improve resource efficiency, reduce waste, and foster sustainable production and consumption. The Action Plan includes initiatives related to product design, waste management, recycling, and resource efficiency, among others. The Action Plan is a key element of the European Green Deal and it is closely linked to the EU Industrial Strategy.

### The plan:

- Aims to promote the transition to a more circular economy in the EU
- Sets out a range of measures to promote the sustainable use of resources, reduce waste, and increase recycling

- 382 • Includes proposals for new legislation, such as an EU-wide framework for the circular  
383 economy, and revisions to existing legislation, such as the WEEE Directive
- 384 • Emphasizes the importance of product design for the circular economy, and proposes  
385 measures to promote eco-design and repairability
- 386 • Includes initiatives to promote the use of secondary raw materials, such as the establish-  
387 ment of a European Raw Materials Alliance
- 388 • Aims to reduce greenhouse gas emissions and improve resource efficiency in the EU
- 389 • Calls for increased cooperation and dialogue among stakeholders in the circular economy.

390 **The Critical Raw Materials Act (CRM act)** [2] is a proposed EU regulation that aims to  
391 ensure a secure and sustainable supply of raw materials to the EU. The Act identifies a list  
392 of strategic raw materials, which are crucial to technologies important to Europe's green and  
393 digital ambitions and for defence and space applications, that are subject to potential supply  
394 risks. The regulation will cover the entire raw materials value chain, from primary extraction to  
395 manufacture to its potential recovery as a secondary raw material.

396 By 2030, one single 'third country' (ex-EU, ex-Schengen) country shall produce not more  
397 than 65% of the EU's annual consumption of each strategic raw material. Clear benchmarks  
398 have been set for domestic capacities of the EU in 2030:

- 399 • Extract at least 10% of the EU's annual consumption
- 400 • Process at least 40% of the EU's annual consumption
- 401 • Recycle at least 15% of the EU's annual consumption

402 These benchmarks have been included in the scenarios developed in FutuRaM. Specifically,  
403 in the Recovery scenario, where the emphasis is on the recovery of materials from waste  
404 streams and the Circularity scenario where the emphasis is on the implementation of 're-X'  
405 strategies, such as recycling, remanufacturing, and reuse. These benchmarks are considered  
406 too optimistic to be included in the Business-as-usual scenario as they suggest near complete  
407 recovery for several elements.

## 408 Waste stream-specific legislation and policy targets

409 With respect to the waste streams that are analysed in FutuRaM, the following waste stream-  
410 specific developments aligned with EU targets have been considered:

- 411 • BATT: Battery and waste battery regulation (2023) [25]
  - 412 – Establishes rules for the collection, treatment, and recycling of batteries and accu-  
413 mulators in the EU
  - 414 – Requires Member States to set up collection and recycling systems for waste bat-  
415 teries and accumulators
  - 416 – Sets specific recycling targets for different types of batteries and accumulators
  - 417 – Prohibits the use of certain hazardous substances in the manufacturing of batteries  
418 and accumulators
  - 419 – Requires labeling and information for consumers on the proper disposal of batteries  
420 and accumulators
  - 421 – Requires producers to take responsibility for the costs of collecting, treating, and  
422 recycling waste batteries and accumulators
  - 423 – Aims to reduce the environmental impact of batteries and accumulators throughout  
424 their life cycle.
- 425 • BATT: Introduction of battery passport in 2026 [26]
- 426 • Mandatory minimum levels of recycled content for industrial, and vehicle batteries.
- 427 • Batteries incorporated in appliances have to be removable and replaceable by 2027.
- 428 • ELV: Proposed revision currently under review [27]:
  - 429 – Sets out rules for the collection, treatment, and recycling of end-of-life vehicles  
430 (ELV) in the EU
  - 431 – Requires Member States to set up collection systems for ELV and ensure that they  
432 are treated and recycled in an more environmentally sound manner.

- 433       – Enforce collection targets, ban export of unroadworthy vehicles.
- 434       – Strengthen ‘Extended Producer Responsibility’ to encourage better quality waste
- 435       treatment.
- 436       – Proposes provisions for design and dismantling of certain CRM-rich components.
- 437   • WEEE Directive (about to be evaluated with a review likely in 2024):
  - 438       – Sets out rules for the collection, treatment, and recycling of waste electrical and
  - 439       electronic equipment (WEEE) in the EU
  - 440       – Requires Member States to establish collection systems for WEEE and ensure that
  - 441       it is treated and recycled in an environmentally sound manner
  - 442       – Sets collection and recycling targets for different types of WEEE
  - 443       – Requires producers to take responsibility for the costs of treating and recycling
  - 444       WEEE
  - 445       – Requires the use of the waste hierarchy for WEEE management
  - 446       – Aims to prevent the generation of WEEE and promote its reuse and recycling
  - 447       – Requires the labeling of electrical and electronic equipment to facilitate its proper
  - 448       disposal.
- 449   • CDW: Inside of the CDW stream are important waste flows such as wind turbines and
- 450   solar panels. The permanent magnets in wind turbines are a source of rare earth elements
- 451   (REEs) and the solar panels contain indium and gallium. The CRM Act will also cover the
- 452   recycling of these waste flows.
- 453   • MIN: The CRM Act will also cover the mining waste stream. As stated by the European
- 454   Commission [\[4\]](#):

455       the Act promotes the recovery of critical raw materials from mining waste. The

456       EU, due to its history of mining, has numerous old mining sites and tailings

457       across the EU which can contain precious critical raw materials, but whose

458       potential has not been analysed so far. The Act obliges current operators

459       to assess the possibility for such recovery and to gather information on the

460       critical raw materials content of the waste they are generating as well as on

the waste stored on their sites. For closed and abandoned mines, the Act makes Member States responsible for gathering this data – from permitting files as well as targeted sampling campaigns – and publishing it in an openly accessible database. This will allow potential operators to identify potential sites of interest and implement such recovery projects with public authorities.

#### **Extent of policy and legislation inclusion in the scenarios**

The targets that result from the planned and ongoing review processes are non-negotiable and legally binding, and thus should be incorporated in our scenarios. These targets, however, are only applicable to post-consumer products, namely WEEE, BAT and ELV. This envisioned future in which legally binding targets for collection, reuse and/or material recycling are achieved can be implemented as the Recovery scenario. If there are no targets set for a specific consumer product category, then approach targets similar to the WEEE directive and in line with the EU Green Deal. For the Recovery, and especially for the Circularity scenario, FutuRaM will also consider the effects of proposed ecodesign requirements for sustainable products (e.g., longer lifetimes, increased reusability, repairability, recyclability).

However, for waste that does not consist of discarded consumer products, but instead results from industrial production activities, in particular for MIN and SLASH, we must still produce specific scenarios related to mining, metallurgy, and waste and fuel combustion. The production of new mining wastes will depend on new local mining activity. Predicted production in the EU until 2050 will be forecast (equally across the three scenarios) and the flows into the MIN waste stream can be calculated with the respective transfer coefficients. The recovery of historical MIN stock, which is target of the CRM Act, should be modelled differently. It requires hypothesis about the percentage of historical tailings recoverable by commodity and country.

The scenarios will account for increasing resource use effectiveness and production process efficiency, thus indicating lower volumes and quality of generated production residues (both by-products and waste such as red mud, waste rock, slags, etc.) per unit of product (expressed either as product mass or product value), whether that product is a metal (e.g., a copper cathode),

489 metal alloy (e.g., aluminium alloy n° 5183) or metal product (e.g., cold rolled stainless steel  
490 sheet).

491 Excepting the BAU storyline, WEEE, ELV, and BATT waste material recovery will follow  
492 the targets in the EU. For SLASH and MIN, we will evaluate recent trends in waste generation  
493 and extract plausible ranges of generation toward 2050. For CDW, embedded WEEE will  
494 follow EU targets, and bulk waste will incorporate storylines and scenarios that are congruent  
495 predicted demolition rates (where renovation is the alternative emphasised in the CIR storyline)  
496 Various drivers will be assigned to move between these ranges and will be key to the specific,  
497 harmonized storyline for the scenario. Finally, the targets and storylines will be aligned with  
498 assumptions on technology development.

#### 499 **Consideration of geopolitical developments**

500 The storylines also attempt to consider geopolitical considerations and thus supply chain  
501 resiliency for satisfying the product demand in the scenarios. We must omit, however, possible  
502 changes in waste flow volumes and composition that could arise from any material supply  
503 constraints. The reasoning for this is that it would needlessly confusate the interpretation  
504 of the modelling results as incertitude of these potentialities is very high and this realm is  
505 outside the scope FutuRaM's mandate and expertise. The most volatile aspect of the 'criticality  
506 calculation' is the risk profile of the producing country. For many material exporting nations,  
507 this is not something that can be reliably forecast, especially not over the next 30 years. Thus, it  
508 will be assumed that the growth in material demand for (among other needs) the energy and  
509 mobility transitions can be satisfied either by an increase in mining and metallurgy activities  
510 within the EU or by growing imports from raw material producing countries outside the EU. That  
511 is, if we go for increased domestic EU production to minimize geopolitical supply risk, it may  
512 indicate more EU production residue generation even under increased production efficiency  
513 and resource effectiveness. The increase of domestic industrial activity, as a response to an  
514 envisioned increased internal demand, supposes an equivalent rise of societal approval for  
515 mining and refining activities on EU territory. If the increased demand is, however, satisfied  
516 by imports from non-EU countries, which we know have domestic resource consumption

also growing significantly due to the energy and mobility transition, our assumption would be to shift the mining and refining activities from EU countries towards resource-rich non-EU countries. This shift would also imply an increased risk for geopolitical instability and/or security of supply of critical raw materials to the EU. This situation is front-of-mind for many in policy and business and EU is 'applying a policy mix that aims to increase domestic capacity, diversify suppliers, and support the multilateral rules-based trade environment.' However, '...most experts predict that reshoring or nearshoring will be of limited importance. With time, though, resilience may improve through international cooperation, diversification and the accelerated uptake of digital technologies.' [28]

**'Note: supply constrictions will be considered in the model's sensitivity analysis and the codebase will be designed to allow for the optimisation of the SRM recovery system based on any supply-demand value statements.'**

## 1.2.2 Step 2: Determine methodology

### Methodology types and selection criteria

The second step in the scenario development process is to determine the methodology to be used. This involves identifying the most appropriate methods and tools for the specific context and objectives of the scenario development process. The methodology should be selected based on the following criteria:

- **Relevance:** The methodology should be relevant to the specific context and objectives of the scenario development process.
- **Applicability:** The methodology should be applicable to the specific context and objectives of the scenario development process.
- **Feasibility:** The methodology should be feasible given the available resources (e.g., time, budget, expertise, data, etc.).
- **Transparency:** The methodology should be transparent and well-documented, allowing

for replication and further analysis.

- **Flexibility:** The methodology should be flexible and adaptable, allowing for updates and adjustments as new information becomes available.
- **Accessibility:** The methodology should be accessible to a wide range of stakeholders, ensuring that it can be understood and used by non-experts.
- **Effectiveness:** The methodology should be effective in achieving the objectives of the scenario development process.
- **Efficiency:** The methodology should be efficient in terms of time, cost, and resources required to implement it.
- **Acceptability:** The methodology should be acceptable to stakeholders, ensuring that it is perceived as fair and legitimate.

Further details are given in this section, and the table in section 5.2 provides an overview of the methods and tools considered, along with a brief description of each and its relevance to the specific context and objectives of the FutuRaM scenario development process.

### Choice of methodology

The grant proposal for the FutuRaM project outlined that there should be at least three scenarios developed, namely business as usual, recovery, and circularity. This remains the case; however, during the scenario development process, additional scenarios or scenario dimensions were considered, including supply chain security and the energy transition.

**Considered dimension — Supply chain security:** Due to various political developments in 2022, the question of the security of the EU's supply chains for CRMs was brought into focus. This led to the proposal from stakeholders to consider a scenario dimension that would explore the security of the EU's supply chains for CRMs.

**Considered dimension — Energy transition:** The energy transition is a key topic in the EU's policy agenda, and the FutuRaM project is concerned with the role of CRMs in the energy

567 transition. Therefore, the proposal was made to consider a scenario dimension that would  
568 explore the energy transition in the EU.

569 **Method — Multi-criteria analysis and cross-impact analysis** In order to assess the potential  
570 inclusion of these additional scenario dimensions, a multi-criteria analysis and a cross-impact  
571 analysis were conducted [29]. The addition of extra dimensions increases the possible number  
572 of scenarios significantly. By assessing the consistency and plausibility of these combina-  
573 tions with a matrix-based method, it was possible to reduce the number of scenarios. For  
574 example, low progress in the energy transition is unlikely to concur with high progress in re-  
575 cycling/circularity indicators and can be excluded. In contrast, different levels for the supply  
576 chain security dimension would result an additional scenario, as this dimension is considered  
577 independent of the others. Ultimately, supply chain security was eliminated as a scenario  
578 demension. This is due to the consortium's inability to speculate on geopolitical developments  
579 and the added incertitude it would introduce to the scenarios. The potential of supply con-  
580 straints will, however, be considered in the future sensitivity analysis of the model, as well as  
581 potentially also through an array of explorative multi-object optimisation procedures. This can  
582 produce projects to answer the question, "What would happen to the SRM system if element x  
583 is constrained, and what would be the optimal response to this constraint?"

584 **Method — Delphi** The Delphi method [30] was used in the initial stages of the scenario  
585 building process to gather and aggregate the opinions of experts or stakeholders. Internal  
586 consultation with consortium members who were experts in their respective waste streams  
587 or other aspects of the recovery system was conducted. The method involves steps such as  
588 the selection of experts, generation of initial questionnaires, iterative rounds of responses,  
589 and convergence and consensus building. For the later stages of the process, further rounds  
590 of consultation will be conducted with external stakeholders, including representatives from  
591 industry, academia, and government.

## 592 **Choice of Scenario Type**

593 The general types of scenarios are summarized in Table 1.3.

594 In the context of futures studies, various approaches and methodologies are employed to  
595 understand the potential trajectories of future developments [6, 7, 20, 21, 22]. We can classify  
596 scenario studies into three primary categories, each addressing distinct questions about the  
597 future. These categories are tailored to better align with the specific objectives of scenario  
598 usage:

599 **Predictive Scenarios (Answering ‘What Will Happen?’):**

- 600 • **Pros:** These scenarios offer insights into potential future outcomes, aiding in long-term  
601 planning.
- 602 • **Cons:** They are contingent on assumptions and may not account for unexpected events.
- 603 • **Applicability:** Predictive scenarios are valuable when the aim is to forecast future devel-  
604 opments under certain conditions.

605 **Explorative Scenarios (Answering ‘What Can Happen?’):**

- 606 • **Pros:** Explorative scenarios explore a wide range of potential future scenarios, fostering  
607 preparedness for various outcomes.
- 608 • **Cons:** They do not prioritize the likelihood or desirability of scenarios.
- 609 • **Applicability:** These scenarios are beneficial when considering multiple potential futures  
610 and the need to adapt to diverse outcomes.

611 **Normative Scenarios (Answering ‘How Can a Specific Target Be Reached?’):**

- 612 • **Pros:** Normative scenarios focus on achieving predefined objectives and offer guidance  
613 on strategies to attain them.
- 614 • **Cons:** They are inherently normative, starting with specific goals in mind.
- 615 • **Applicability:** Normative scenarios are suitable when the objective is to work towards  
616 predefined targets and develop actionable plans to reach them.

617 The choice of scenario category is influenced not only by the characteristics of the system  
618 under study but also by the user's worldview, perceptions, and study objectives. Additionally,  
619 the user's perspective plays a crucial role in determining the most suitable approach. For  
620 instance, the decision to employ predictive, explorative, or normative scenarios hinges on the  
621 user's goals and the nature of the questions they seek to answer.

622 Furthermore, considerations regarding the predictability of the future and the potential for  
623 influencing it can impact the selection of scenario types. For example, some users may argue  
624 that uncertainty in certain parameters makes long-term predictions less meaningful, while  
625 others may see value in using forecasting and optimisation models to stimulate discussions  
626 and inform decision-making processes.

627 In practice, a combination of qualitative and quantitative techniques can be employed to  
628 create scenarios tailored to specific needs. For instance, a blend of techniques may be used to  
629 generate forecasts, especially when external factors are uncertain. Likewise, strategic scenarios  
630 often begin with external scenario generation and proceed to identify available policy options.

631 The choice of scenario category is driven by the user's objectives, worldview, and perceptions,  
632 making it a crucial factor in the scenario selection process. This user-centric approach ensures  
633 that scenarios are not only relevant but also effectively inform decision-making processes.  
634 While further refinement is needed based on user feedback, this report provides valuable  
635 guidance for scenario usage.

Table 1.3: Types of scenario (adapted from [6])

Scenario category	Scenario type	Quantitative/qualitative	Time-frame	System structure	Focus on internal or external factors
Predictive <i>what will happen?</i>	Forecasts	Typically quantitative, sometimes qualitative	Often short	Typically one	Typically external
	What-if	Typically quantitative, sometimes qualitative	Often short	One to several	External and, possibly, internal
Explorative <i>what can happen?</i>	External	Typically qualitative, quantitatively possible	Often long	Often several	External
	Strategic	Qualitative and quantitative	Often long	Often several	Internal under influence of the external
Normative <i>how can a target be reached?</i>	Preserving	Typically quantitative	Often long	One	Both external and internal
	Transforming	Typically qualitative with quantitative elements	Often very long	Changing, can be several	Not applicable

636 The scenarios developed in the FutuRaM project are a combination of predictive and  
637 normative:

638 • **BAU:**

639 *What will happen if current trends continue?*

640 This scenario is predictive in nature, based on the assumption that the current trends and  
641 developments in waste management and resource recovery systems will continue into  
642 the future.

643 • **Recovery:**

644 *What will it take to achieve the EU's targets for material use and recovery?*

645 *Focus on technology*

646 This scenario is normative, focusing on manipulating the technology and infrastructure  
647 of the recovery system to achieve the EU's targets and mandates.

648 • **Circularity:**

649 *What will it take to achieve the EU's targets for material use and recovery?*

650 *Focus on re-X strategies*

651 This scenario is a combination of normative and explorative, considering the targets and  
652 mandates of the EU's circular economy action plan and exploring re-X strategies in the  
653 recovery system.

654 The methodology and scenario types were selected based on their relevance, applicability,  
655 feasibility, transparency, flexibility, accessibility, effectiveness, efficiency, and acceptability to  
656 the scenario development process.

657 **1.2.3 Step 3: Marker-scenario mapping**

658 **Justification and methodology**

659 This preliminary step in the scenario development process involves conducting a literature  
660 study to identify existing scenarios that are relevant to the FutuRaM project. This step is crucial

as it serves several important purposes and provides valuable insights for the overall scenario development process. It helps the scenario development team to build on existing knowledge, identify relevant scenarios, gain insights and inspiration, fill knowledge gaps, and enhance credibility and comparability.

**Building on existing knowledge:**

Conducting a literature study allows the FutuRaM project team to tap into existing knowledge and expertise in the field of waste management, resource recovery, and circular economy. It provides a foundation of existing scenarios that have been developed by other researchers, organizations, or institutions. By building on this existing knowledge, the FutuRaM project can leverage the insights, methodologies, and findings from previous scenario studies, saving time and resources.

**Identifying relevant scenarios:**

Marker scenario mapping helps identify scenarios that are relevant to the specific objectives and scope of the FutuRaM project. By reviewing the literature, the project team can assess the applicability of existing scenarios to their research questions and determine which scenarios align with the waste streams, sectors, and policy domains being considered. This step ensures that the scenarios selected for further analysis are well-suited to address the project's goals.

**Gaining insights and inspiration:**

Reviewing existing scenarios provides the FutuRaM project team with valuable insights and inspiration for the development of their own scenarios. It allows them to understand the different approaches, assumptions, and methodologies used in previous scenario studies. This knowledge can inform the design and structure of the FutuRaM scenarios, helping to ensure a rigorous and well-founded approach.

**Filling knowledge gaps:**

Marker scenario mapping helps identify any gaps or areas of limited knowledge in the existing scenario landscape. It allows the FutuRaM project team to identify topics or aspects that have not been adequately addressed in previous scenarios. This awareness of knowledge gaps can guide the project team in focusing their efforts on areas where new insights and contributions can be made, leading to a more comprehensive and innovative scenario development process.

**Enhancing credibility and comparability:**

By conducting a literature study and referencing existing scenarios, the FutuRaM project can enhance the credibility and comparability of their own scenarios. The project team can reference and compare their findings, assumptions, and results with those from previous studies, contributing to the overall body of knowledge in the field. This promotes transparency, robustness, and consistency in the scenario development process and allows for better benchmarking and evaluation of the FutuRaM scenarios.

**Content of the marker scenario mapping for application to FutuRaM's scenarios**

section 5.3 presents an overview of the marker scenarios considered in the FutuRaM project. The table is not intended to be exhaustive but rather to provide an overview of the different scenarios that have been developed in the field of waste management, resource recovery, and circular economy.

**1.2.4 Step 4: Identification of key drivers of change**

In this step, the key drivers of change that will shape the future of the scenarios are identified. Key drivers are the factors or forces that have a significant influence on the waste management system and its development over time. These drivers can be social, economic, technological, environmental, or policy-related.

The purpose of identifying key drivers of change is to understand the factors that will have the greatest impact on waste management and to ensure that the scenarios capture the range of possible outcomes influenced by these drivers.

The process of identifying key drivers involves a combination of literature review, expert consultations, and stakeholder engagement. It requires a comprehensive analysis of relevant trends, uncertainties, and emerging issues that may affect the waste management system.

The key drivers identified in this step will be used to develop the storyline themes and scenario parameters in the next step.

Figure 1.2 illustrates the process of identifying key drivers of change.

### Methodology and results of this stage in FutuRaMs scenario development:

The overall goal of this process is to identify and include elements in the storylines and scenarios that are relevant, plausible, and influential in shaping the future. The selection, screening, and categorization steps ensure that the elements chosen for the development of storylines and scenarios are consistent, coherent, and aligned with the objectives and scope of the scenario exercise.

#### 1. Preliminary collection:

This step involved gathering a pool of potential elements that could be included in the storylines and scenarios. These elements were derived from expert input from waste streams and the scenario development team including taking also knowledge from the literature review and existing scenarios identified in Step 2 — Marker scenario mapping.

This step was conducted using the PESTLE analysis framework. The PESTEL (or PESTLE) framework is a strategic tool used to understand the macro-environmental factors that can affect a system. A PESTEL analysis can help identify opportunities and threats linked to each of these factors, understand the broader context and shape scenarios accordingly [31, 32].

The acronym PESTEL stands for:

- **Political:** These factors refer to the impact of government policies, regulations, and political stability. This includes issues like tax policy, labour laws, environmental regulations, trade restrictions and reforms, tariffs, and political stability.
- **Economic:** These factors relate to the broader economic environment, including factors like economic growth, exchange rates, inflation rates, interest rates, disposable income of consumers and businesses, and the general health of the economy.
- **Sociocultural:** These factors include societal trends and characteristics that could affect your business. They include demographic trends (like age, gender, and ethnic-

ity), cultural trends, lifestyle preferences, consumer attitudes, and broader societal expectations.

- **Technological:** These factors refer to the impact of emerging technologies, research and development activities, automation, the rate of technological change, and the adoption of technology within your market.
- **Environmental:** These factors refer to ecological aspects that can affect a system. This includes environmental regulations, consumer attitudes towards sustainability, climate change, and other natural events.
- **Legal:** These factors include laws and regulations with which your business must comply. These can include labour law, consumer law, health and safety law, and restrictions on the import or export of goods.

The 68 elements identified in the initial screening stage are listed in section 5.4.

## 2. Screening:

In the screening step, the collected elements are evaluated and assessed based on specific criteria. This was conducted through an literature study and internal consultation of scientists in the project. This evaluation helps determine the relevance, reliability, and significance of each element for the development of storylines and scenarios. Many elements were aggregated, especially if they were deemed to follow similar trends to others (e.g., recyclability mandates and improved recyclability in project design). Elements that did not meet the predefined criteria or were deemed irrelevant, unmodellable or unreliable were be excluded from further consideration (e.g., corruption, data protection, and supply chain conflict).

The 28 elements that were identified in this stage are listed in section 5.5.

In Figure 1.3, an excerpt of a spreadsheet illustrates part of the screening process for the FutuRaM scenarios which was informed by the waste streams. In this exercise, the elements were evaluated based on their relevance to the waste streams and their potential impact on the waste management system. The elements were also assessed based on their plausibility and likelihood of occurrence in the future. The elements that

769        were deemed relevant, plausible, and influential were included in the storylines and  
770        scenarios.

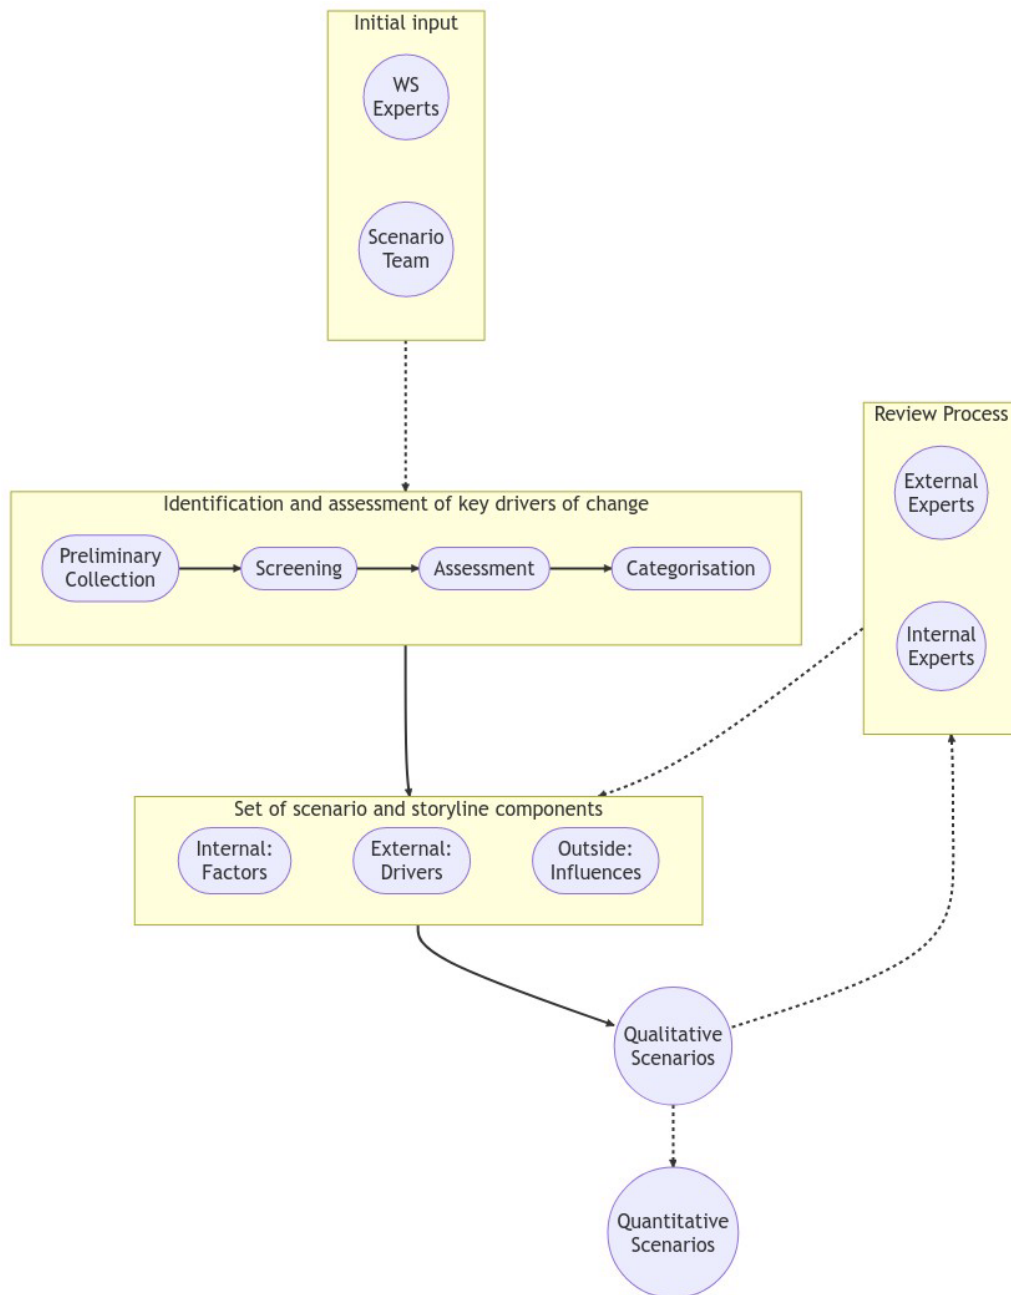

Figure 1.2: An illustration of the process used for identifying key drivers of change

THIS TABLE IS FOR THE ASSESSMENT OF THE RELEVANCE OF EACH SCENARIO ELEMENT TO INDIVIDUAL WASTE STREAM FLOWS	ELV			BAT					WEEE					
	Bulk metals	Critical raw materials	Average	Portable Batteries	Industrial Batteries	Automotive (SLI) Batteries	EV Batteries	Average	CAT-I - Temperature exchange	CAT-II Screens	CAT-III Lamps	CAT-IVa Large equipments	CAT-IVb PV	CAT-V Small equipments

Figure 1.3: Excerpt of a spreadsheet used as part of the screening process

### 771 3. Assessment

772 Once the screening process was complete, the remaining elements were aggregated and  
773 categorised based on their thematic relevance or characteristics. This categorisation helps  
774 organize the elements into meaningful groups or themes that align with the objectives  
775 and scope of the scenarios.

776 The 21 elements that were identified in this stage are listed in Table 1.4. Note that CIR  
777 and REC are very similar, they main difference being the way in which the targets are  
778 achieved. That is, for CIR, re-X strategies are promoted, whereas for REC, the focus  
779 is on technological advancements in the recovery system. This distinction will have a  
780 significant impact on how the scenarios are quantitatively modelled.

Table 1.4: Key drivers of change identified in the screening stage (the numerals indicate the degree to which the drivers are present in each scenario, 'n/a' signifies that the driver will not be assessed directly in the scenario modelling)

Element	Domain	Definition	Internal	BAU	REC	CIR
Recovery technology	TECH	Implementation and advancements in waste recovery technologies	TRUE	I	III	III
Product technology	TECH	Changes in product function or composition	TRUE	I	III	III
Integration of SRM system across EU	TECH	Integration of a secondary raw material recovery system across EU countries	TRUE	I	III	III
Increased drive for environmental protection	ENV	Growing concern and motivation for environmental conservation	TRUE	I	III	III
Progress toward renewable energy targets	ECO	Advancements and achievements in renewable energy generation	TRUE	III	III	III
Subsidies/taxation to promote circularity	ECO	Financial incentives or taxes to encourage circular economy	TRUE	I	II	III

Continued on next page

Table 1.4 — Continued from previous page

Element	Domain	Definition	Internal	BAU	REC	CIR
Participation in re-X activities	SOC	Engagement in refuse-reduce-repair-reuse activities	TRUE	I	I	III
Stricter environmental regulations	POL	Tightening of environmental laws and regulations	TRUE	II	III	III
Stricter waste management regulations	POL	Strengthening of waste management laws and regulations	TRUE	II	III	III
Supply chain due diligence laws: implementation and enforcement	POL	Obligations for identifying and mitigating negative impacts in supply chains	TRUE	O	III	III
Compliance with waste targets	POL	Meeting specific waste management and recycling targets	TRUE	O	III	III
Resource shortages	ENV	Limited availability of natural resources	FALSE	n/a	n/a	n/a
Raw material vs SRM prices	ECO	Price dynamics and competition between raw materials and secondary raw materials	FALSE	n/a	n/a	n/a
Climate change impacts/mitigation	ENV	Effects and actions related to climate change	FALSE	n/a	n/a	n/a
International trade and co-operation (vs. autarky)	ECO	Collaborative trade agreements and global cooperation	FALSE	n/a	n/a	n/a

Element	Domain	Definition	Internal	BAU	REC	CIR
Energy prices	ECO	Costs and fluctuations in energy prices	FALSE	n/a	n/a	n/a
Economic growth	ECO	Overall economic expansion and development	FALSE	n/a	n/a	n/a
Re-industrialisation of EU	ECO	Shift towards increased industrial activities in the EU	FALSE	n/a	n/a	n/a
NIMBY to projects	SOC	Opposition to local projects and developments	FALSE	n/a	n/a	n/a
Population and Urbanisation	SOC	Growth and urban development of population	FALSE	n/a	n/a	n/a
CO2 market price	ECO	Price and market dynamics of carbon emissions	TRUE	n/a	n/a	n/a

#### 781 4. Categorisation

782 The scenario elements were then assessed based on their potential impact on the waste  
783 management system. For each element, an assessment was made as to whether it was  
784 within the scope of FutuRaM to include them as variables in the models, and therefore  
785 also the scenarios and their storylines. Those deemed to be within the scope are 'internal'  
786 and will be intensively researched and modelled (e.g., composition and design changes).  
787 Those deemed to be outside the scope are 'external' and will be included in the storylines,  
788 will vary over time, but will not vary across the three scenarios (e.g., population and  
789 GPD). Those deemed to be outside the scope and also outside the influence of the  
790 waste management system are 'outside' and will not be included in the storylines or  
791 scenarios, though, in some cases, may be considered in the sensitivity analysis (e.g.,  
792 supply constraints).

#### 793 Justification for keeping elements outside of the scenario models:

794 The purpose of the FutuRaM project is not to provide all-encompassing scenarios that attempt  
795 to capture every possible future development. Such scenarios are inherently inaccurate and  
796 can give a false sense of certainty to the model's outcomes. Instead, the focus of FutuRaM is  
797 specifically on the Sustainable Resource Management (SRM) system and its implications for  
798 the future. Therefore, the scenarios developed within FutuRaM should selectively incorporate  
799 elements that have a direct impact on the SRM system.

800 Furthermore, the scenarios should prioritize elements that can be considered as 'policy  
801 knobs', meaning variables or factors that can be adjusted or controlled to test different settings.  
802 By including these, the scenarios can explore the effects of different policy decisions or inter-  
803 ventions on the SRM system's outcomes. This targeted approach ensures that the scenarios  
804 generated are relevant to the project's objectives and facilitate meaningful analysis.

805 It is crucial to avoid excessive complexity and convolution in scenario modelling. When  
806 there are too many convoluted elements included, the results of the modelling exercise can  
807 become, at best, difficult to understand and interpret. At worst, the outcomes may become

808 practically useless due to the overwhelming interactions and uncertainties introduced by the  
809 complex elements. Therefore, careful consideration is necessary to strike a balance between  
810 incorporating essential factors and maintaining the clarity and usefulness of the scenario  
811 modelling results.

## 812 **Examples:**

### 813 • **Resource shortages:**

814 Resource shortages can be highly unpredictable and subject to various external factors  
815 such as geopolitical events, natural disasters, or technological advancements. The precise  
816 timing and extent of resource shortages are challenging to forecast accurately, making it  
817 difficult to include them within the model without introducing significant uncertainty.  
818 This is especially true for the long-term time horizon of the FutuRaM scenarios. This factor  
819 will, however, be considered in the sensitivity analysis of the model and additionally, the  
820 codebase will be designed to allow for the optimisation of the SRM recovery system  
821 based on any supply-demand value statements.

### 822 • **Raw material vs SRM prices:**

823 The dynamics and competition between raw materials and secondary raw materials  
824 can be complex and influenced by various market factors, technological advancements  
825 and policy interventions. As with resource shortages, these dynamics are challenging  
826 to forecast accurately, making it difficult to include them within the model without  
827 introducing significant uncertainty. It will, however, be possible to couple the model  
828 with a market model to explore the effects of different price dynamics on the SRM  
829 system's outcomes. This could be considered in a multi objective optimisation procedure  
830 performed as an extension to the model.

## 831 **Conclusion**

832 The methodology used for the FutuRaM scenario development ensured that the selected  
833 elements were relevant, plausible, and influential. The use of the PESTEL analysis framework

834 and Delpi method during the preliminary collection phase provided a comprehensive overview  
835 of the macro-environmental factors. Furthermore, the screening process and the assessment  
836 by internal experts ensured that the selected elements were coherent, consistent, and aligned  
837 with the objectives and scope of the scenario exercise. The final list of scenario elements is  
838 suited to the goal of the FutuRaM project — to quantify the future availability of SRMs and to  
839 evaluate EU material autonomy — and will be used to develop the three FutuRaM scenarios  
840 into a quantitative model.

#### 841 **1.2.5 Step 5: Develop storyline themes**

842 Given that the scenario themes and directions were broadly dictated by the FutuRaM project  
843 charter, the rough shapes of the storyline narratives were already defined. That is: the ef-  
844 fects on the availability of SRMs from the development of the SRM recovery system and the  
845 development of re-X strategies.

#### 846 **1.2.6 Step 6: Qualitative narrative development**

847 The scenario storylines will be described in detail in the next section. This step involved taking  
848 the themes defined by the charter and the elements identified in the previous steps and  
849 working with the internal waste stream groups to develop qualitative estimates about how  
850 each of these elements (at their different levels) may have an impact on the amounts and  
851 composition of the SRM flows in their purview.

#### 852 **1.2.7 Step 7: Definition of scenario parameters**

853 The scenario parameters are the set of quantitative values or functions that will be used to  
854 define the scenario inputs for the model. These parameters will be defined in the next stages  
855 of the project.

### 856 1.2.8 Step 8: Quantitative modelling

857 The scenario quantification will be performed in the next stages of the project.

### 858 1.2.9 Step 9: Implementation

859 The scenario implementation will be performed in the next stages of the project.

### 860 1.2.10 Step 10: Review process

861 The review process is intended to ensure that the elements included in the storylines and  
862 scenarios are relevant, plausible, and consistent with the scenario objectives and scope.

863 The first stage of the review process is to open the scenario development process to the  
864 wider FutuRaM consortium. This will be done by sharing the scenario development process and  
865 the results of the assessment and categorization step with the consortium and inviting feedback  
866 and suggestions. The feedback will be used to refine the elements and their categorization and  
867 to identify any elements that may have been missed in the initial assessment.

868 The second stage will involve opening the scenario development process to external stake-  
869 holders and subject matter experts.

870 The scenario review process will be performed repeatedly over all stages of the project.  
871 This document is a living document and will be updated as the project progresses.

## 872 **Chapter 2**

## 873 **Scenario storylines**

## 874 2.1 Scenario 1: Business as usual

### 875 2.1.1 Storyline narrative

876 This scenario envisions the future based on the current situation, extending to 2050 with very  
877 little deviation from present consumption patterns and the secondary raw material (SRM)  
878 system [33]. While there may be advances in some areas such as resource efficiency, recovery  
879 technology, and the energy transition, substantial modifications remain hindered by economic,  
880 social, and political constraints. The primary extraction of raw materials continues to be the  
881 primary source to meet the EU's demand.

882 In the Business As Usual (BAU) scenario, we are projecting the trajectory of the present into  
883 the future, extending up to the mid-century mark, 2050, with minimal disruption to existing  
884 consumption habits and the secondary raw material (SRM) system. This scenario unfolds on  
885 the assumption that the current pace and direction of technological, economic, and social  
886 development continue unhindered, and is characterised by a strong persistence of today's  
887 patterns.

888 In this scenario, we see moderate improvements in resource efficiency, advancements in  
889 recovery technology, and a slow transition towards greener energy sources. However, these  
890 developments are only minor tweaks to the existing system, failing to disrupt or fundamentally  
891 alter the established structure. The potential for transformational change remains largely  
892 untapped due to various hurdles. Economic constraints, social resistance to change, political  
893 inertia, and entrenched interests act as barriers to change, stifling efforts towards a more  
894 sustainable SRM system.

895 Primary extraction of raw materials remains the dominant source for raw materials con-  
896 sumed in the EU, continuing the linear 'take-make-dispose' model of resource consumption.  
897 Base metals are well recycled, given their developed markets and economies of scale but  
898 rare/special metals are wasted because recycling technologies and economics does not allow  
899 their recovery. Recycling and recovery rates remain stubbornly low, resulting in significant CRM  
900 waste. Meanwhile, material demand continues to rise in tandem with GDP growth, further

901 exacerbating the resource pressure.

902 Moreover, the environmental impacts of mining and extraction persist as a significant  
903 concern. These operations continue to degrade ecosystems, leading to loss of biodiversity and  
904 contributing to climate change [34]. Simultaneously, the EU becomes increasingly dependent  
905 on imports of SRMs, raising concerns about supply chain security and geopolitical risks [34].

906 Innovation in SRM recovery technologies is hampered by a lack of investment and regulatory  
907 support. The focus remains predominantly on cost-effective material production and use, with  
908 little regard for environmental implications or long-term sustainability. Material scarcity and  
909 price fluctuations, therefore, may become a considerable risk to the EU industry, limiting stable  
910 penetration of new recovery technology and threatening economic stability.

911 Moreover, the tightening of environmental regulations is restricted, inadequately addressing  
912 emerging challenges or incentivising sustainable practices. The lack of regulatory progress may  
913 further exacerbate environmental damage and biodiversity loss.

914 In essence, the BAU scenario is characterised by a continuation of current trends and  
915 practices, a future where the potential for a sustainable SRM system is unrealised due to the  
916 stranglehold of prevailing economic, social, and political constraints.

917 In the Business as usual (linear economy) scenario, the following are key characteristics:

- 918 • A forecasting model is used to predict the future based on the current situation and the  
919 development of existing trends.
- 920 • Many EU targets for recycling and recovery are not met, and the current linear model  
921 largely persists.
- 922 • Material demand keeps pace with GDP growth, perpetuating a trend of increasing con-  
923 sumption. Primary mining and extraction persist as the leading sources of raw materials,  
924 underlining the dependency on traditional extraction methods.
- 925 • Recycling and recovery rates continue to lag, leading to an accumulation of SRM waste  
926 that signals missed opportunities for resource reuse.

- 927 • The environmental repercussions of mining and extraction, such as land degradation and  
928 water pollution, continue to be a pressing concern, reflecting the ecological toll of this  
929 linear model.
- 930 • The EU's dependency on imports of SRMs escalates, heightening the risk of supply  
931 disruptions. While supply disruption can serve to stimulate investment in new SRM  
932 recovery, volatility stifles innovation and advancements in this field.
- 933 • The industrial focus remains on cost-effective material production and use, disregarding  
934 the long-term sustainability aspect.

### 935 2.1.2 Waste stream specific scenario impacts

#### 936 BATT (Battery waste) [11, 12, 25, 26]

937 In the business as usual (BAU) scenario, the management of end-of-life batteries remains  
938 largely unchanged. The lack of technological innovation and regulatory incentives lead to a  
939 continued low recovery rate of valuable materials from battery waste.

- 940 • A growing volume of battery waste due to the increased use of electronic transport and  
941 renewable energy storage systems.
- 942 • Lack of technological innovation and regulatory incentives lead to low recovery rates for  
943 certain battery types and certain elements.
- 944 • Collection systems for battery waste remain sporadic and unstandardised.
- 945 • Primary extraction remains the dominant source for battery materials.
- 946 • Share of LIB will increase (EV, LMT, Industrial LIB uptake)
- 947 • LIB Battery Chemistries will change and new LIB technologies will enter the market.  
948 Though, not with a focus on recycling and recovery.
- 949 • Larger portable batteries: shift towards Li-ion batteries
- 950 • Small format batteries in EEE: no significant change in battery chemistry.

- 951 • Use of critical resources continue but are already decreasing (BATT chemistry already  
952 changing towards less CRM content)
- 953 • Large scale reuse of batteries is minimal
- 954 • Collection rates do not fulfil the EU targets
- 955 • Recycling efficiencies do not fulfil the EU targets
- 956 • Recovery rates do not fulfil the EU targets

957 **ELV (End-of-Life Vehicles) [12, 27, 35, 36, 37]**

958 The BAU scenario maintains the current approach to end-of-life vehicles, with minimal  
959 improvements in the recovery and recycling process. The absence of effective technologies  
960 and regulatory incentives results in low recovery rates of valuable materials from ELVs.

- 961 • Legislation banning new ICEVs from 2035
- 962 • Current recovery technologies are unable to significantly improve the extraction of  
963 valuable materials from ELVs.
- 964 • Consumer demand continues to drive high production of new vehicles.
- 965 • ELV collection systems remain at their current efficiency.
- 966 • A significant proportion of vehicle components continue to end up as waste.
- 967 • Gradual and slow improvement of recycling chain technology efficiency
- 968 • No new legislation to improve recovery and support circular strategies in comparison to  
969 2023

970 **WEEE (Waste Electrical and Electronic Equipment) [38, 39, 40, 41, 42]**

971 In the BAU scenario, the treatment of WEEE does not significantly change. The lack of  
972 technological progress and effective regulation results in low recovery rates of valuable materials  
973 from WEEE.

- 974 • Limited improvements in the recovery of valuable materials from WEEE.
- 975 • High consumer demand for new electronics continues to drive high WEEE generation.
- 976 • Ineffective collection systems and lack of public interest result in significant amounts of  
977 WEEE ending up in landfills.
- 978 • No significantly growth in collaboration between government and industry for WEEE  
979 recovery.
- 980 • The majority of WEEE continues to be treated with common domestic waste, with low  
981 recycling rates.
- 982 • No ground breaking technologies and practices to improve recovery and circularity.
- 983 • Reuse of products and components is not widely utilised
- 984 • Changes in legislation (e.g., circular economy and product design targets, targets for  
985 collection and recycling) are not strictly implemented.
- 986 • The BAU and the Recovery scenarios are similar from the put-on-market perspective  
987 (e.g., production and consumption remain the same), but it's the recovery stage that  
988 makes the difference.

#### 989 **Mining waste (MIN)**

990 The BAU scenario sees the continuation of current practices in mining waste management.  
991 The absence of advanced recovery technologies and regulatory incentives leads to low recovery  
992 rates of valuable materials from mining waste.

- 993 • Limited technological advancements lead to static recovery rates of valuable materials  
994 from mining waste.
- 995 • Continued reliance on primary extraction as the dominant source of raw materials.
- 996 • Minimal advances in collaboration between government and industry for mining waste  
997 recovery.

- 998 • Low levels of traceability and management of mining waste.
- 999 • Mining waste remains a significant environmental challenge.
- 1000 • Mining waste recovery projects remain too expensive.
- 1001 • Little incentive for private sector and public sector, except for monitoring environmental
- 1002 risks of existing deposits.

#### 1003 **CDW (Construction and Demolition Waste) [43]**

1004 In the BAU scenario, the management of Construction and Demolition Waste (CDW)  
 1005 remains largely unchanged. Lack of progress in recovery technologies and regulatory incentives  
 1006 lead to low recovery rates of CRM containing materials from CDW.

- 1007 • Base metals are recovered as they have been [44], though there are limited improvements
- 1008 and no particular focus on the recovery of CRMs from CDW.
- 1009 • Continued generation of CDW due to the demand in the construction sector.
- 1010 • Renovation as an alternative to new construction is not widely adopted.
- 1011 • The majority of CDW (excluding base metals) continues to be treated as waste or backfill,
- 1012 with low recycling rates.
- 1013 • CDW recovery (including preparation for re-use, recycling and other material recovery,
- 1014 including backfilling)
- 1015 • Recovery of metals remains on already high levels (>90%)
- 1016 • Recovery of minerals remains on already high levels (>70%) by using them as aggregates
- 1017 in road construction and backfilling
- 1018 • Recycling of wind turbines stays around 85% (mainly metals), permanent magnets
- 1019 continue to be recycled as part of the metal fractions

#### 1020 **SLASH (Slags and Ashes)**

1021 In the BAU scenario, SLASH continue to be treated generally as low or negative value waste.  
 1022 The absence of economically profitable recovery technologies or regulatory mandates leads to  
 1023 low improvements in recovery rates of CRMs from SLASH.

1024 • Increased generation of SLASH because SRMs are not recovered and end up in incinera-  
 1025 tion and smelter residues.

1026 • Low quality of SLASH due to:

1027 – poor sorting and separation of waste streams (e.g., consumer electronics, batteries,  
 1028 end up in general waste streams and are incinerated)

1029 – high 'contamination' from the above described failures of segregation.

1030 – large proportion coming from mixed waste incineration

1031 • Lack of technological advancements result in low recovery rates of valuable materials  
 1032 from SLASH.

1033 • Continued high generation of SLASH due to the reliance on traditional energy sources.

1034 • Minimal incentives for the recovery and reuse of materials from SLASH.

1035 • Low levels of traceability and management of SLASH.

1036 • SLASH continues to be a significant environmental challenge due to the high volume  
 1037 generated.

1038 • Some products from SLASH are recovered in low added value, for example, as aggregates  
 1039 for roads or additives in cement.

## 1040 2.2 Scenario 2: Recovery

### 1041 2.2.1 Storyline narrative

1042 In the recovery scenario, the central emphasis is on harnessing sophisticated technologies to  
 1043 salvage SRMs from waste streams at the end of their lifecycle. While there are noticeable strides

1044 towards the incorporation of 'circular design' principles and re-X strategies, they are mostly  
1045 seen at the end-of-life and material demand is akin to that observed in the BAU scenario. This  
1046 is however, mitigated by the implementation of a comprehensive material recovery system.

1047 In this scenario, the central actor is the waste treatment sector, with the spotlight falling on  
1048 the enhancement of recovery technology. The implementation and optimisation of cutting-  
1049 edge technologies, such as Artificial Intelligence (AI), automation, and advanced robotics, play  
1050 a significant role in revolutionising waste treatment processes. These technologies streamline  
1051 waste sorting, improve the quality of recovered materials, and increase the overall efficiency of  
1052 the recovery process.

1053 This scenario calls for an emphasis on policy development and standardisation to foster  
1054 EU-wide development, integration, and compliance. Here, the role of governments and policy-  
1055 makers becomes crucial in setting more ambitious recovery targets, developing conducive  
1056 regulatory frameworks, and enforcing compliance. This multi-pronged approach also involves  
1057 strengthening cross-border cooperation, harmonising waste management standards, and  
1058 promoting knowledge and technology transfer among EU member states.

1059 To realise more ambitious environmental impact reduction targets, significant progress  
1060 needs to be made in both technological and policy aspects. Enhancing technological capabilities  
1061 will improve recovery rates, while robust policy measures will ensure these advancements are  
1062 integrated into the wider economy in a regulated manner. The future of this scenario depends  
1063 on the successful fusion of advanced technology, regulatory harmonisation, and a commitment  
1064 to continuous improvement in waste management and SRM recovery.

1065 Key characteristics of this technology promoted recovery scenario include:

- 1066 • This scenario uses a combination of the forecasting and backcasting methods to envision  
1067 the future.
- 1068 • The backcasting method is used for scenario factors that are covered by governmental  
1069 targets, starting with the desired outcome and working backwards to the present.
- 1070 • The forecasting method is used for scenario factors that are not covered by governmental  
1071 targets, starting with the current situation and extending to the future.

- 1072 • EU targets for recycling and recovery are met, due to the EU's waste management system  
1073 becoming more expansive, efficient and effective.
- 1074 • Technological innovation drives increased recovery rates of SRMs, enabling the more  
1075 efficient use of waste.
- 1076 • Digitalisation and automation are more extensively used in recycling processes, leading  
1077 to enhanced productivity and accuracy.
- 1078 • There is greater exploration and exploitation of alternative sources such as urban mining,  
1079 waste streams, and tailings, presenting novel opportunities for resource acquisition.
- 1080 • New waste regulations and guidelines for SRM recovery are implemented, enforcing  
1081 better management and extraction of SRMs.
- 1082 • Investment in research and development for SRM recovery technologies experiences an  
1083 upswing, promoting continuous innovation in this field.
- 1084 • Closer collaboration and information sharing between industry and government institu-  
1085 tions streamline processes and expedite decision-making.
- 1086 • New jobs are created in the recycling and recovery sector, offering economic benefits  
1087 and improving overall employment rates.
- 1088 • SRM production and use become more efficient and cost-effective, fostering economic  
1089 sustainability.
- 1090 • Environmental impact from mining and extraction is reduced, signaling a more sustain-  
1091 able approach to resource acquisition.
- 1092 • The EU's dependence on primary extraction is reduced, with SRM recovery becoming a  
1093 more significant source of raw materials.

### 1094 2.2.2 Waste stream specific scenario impacts

1095 BATT (Battery waste) [11, 12, 25, 26]

Under the recovery scenario, end-of-life batteries become a crucial source of secondary raw materials, primarily due to the increased adoption of electric vehicles and renewable energy storage systems. Technological innovation drives the recovery and recycling process, ensuring valuable materials are extracted from waste batteries for reuse.

- Increase in end-of-life batteries due to the growth of electric vehicles and renewable energy storage.
- Advanced recovery technologies facilitate efficient extraction of valuable materials from battery waste.
- Standardised collection systems enhance the quantity and quality of battery waste available for recovery.
- Industry and government collaboration leads to investments in research and development of battery recovery technologies.
- Battery passport have a strong impact on collection, material recovery rates and recycling rates.
- Collection
  - Portable batteries collection increase according to the trend seen in the WEEE waste stream.
  - Improved collection of light means of transport (LMT) batteries.
  - Improved regulation and collection of Industrial batteries.
- Material recovery
  - Improved recycling technologies
  - Battery Pass will improve material recovery
  - Higher recovery rate for lithium
  - Increase in recycling by average weight
  - Recycling of plastics
- Ambitious goals of recycling/recovery rates compete with re-use, so re-use remains low.

- 1122 • Improved public awareness means that fewer batteries end up in the municipal waste  
1123 stream and there is less hoarding.
- 1124 • Against this: there is competition for the batteries from the re-use vs. recycling market.
- 1125 • Design for recycling (DFR):
  - 1126 – Material and composition selection for recycling [12].
  - 1127 – Higher requirements on disassemblability.
  - 1128 – Information available to promote efficient recovery.

#### 1129 **ELV (End-of-Life Vehicles) [12, 27, 35, 36, 37]**

1130 The recovery scenario envisions a more effective and technology-driven end-of-life vehicle  
1131 treatment process. Advancements in recovery technologies allow for an improved extraction  
1132 of valuable materials from vehicles at their end of life, although consumerism still drives high  
1133 demand for new vehicles.

- 1134 • Innovations in recovery technologies allow for a higher recovery rate of CRM containing  
1135 materials from ELVs.
- 1136 • The total number of vehicles produced remains high due to consumer demand.
- 1137 • Improved systems for ELV collection are established, ensuring efficient management of  
1138 ELV waste.
- 1139 • Increased collaboration between the government and industry leads to investments in  
1140 ELV recovery technologies.
- 1141 • Focus on managing end-of-life of vehicles
- 1142 • EU recovery targets are reached (currently implemented/proposed targets, but also  
1143 increased and new targets)
- 1144 • Common/bulk materials (Fe, Non-Fe, plastics etc.) and precious metals (Au, Ag, Pd, Pt)  
1145 reach high mass recycling rates and high element recycling rates. Other CRMs currently  
1146 not recovered reach a moderate level of recovery.

- 1147 • For instance,
  - 1148 – More advanced dismantling and processing steps (e.g., components and materials)
  - 1149 – More specialised recovery of certain components and materials (e.g., electric motors
  - 1150 including permanent magnets and embedded REE) as suggested in the proposal
  - 1151 for a revised ELV directive.
  - 1152 – More public and private interest in developing recycling chains
  - 1153 – Increase in collection rate due to increase in participation from public and businesses,
  - 1154 i.e., target-based incentives with strong regulations and monitoring
- 1155 • Design for recycling (DFR):
  - 1156 – Higher requirements on ‘disassemblability’.
  - 1157 – Information available to enable recovery.

#### 1158 **WEEE (Waste Electrical and Electronic Equipment) [38, 39, 40, 41, 42]**

1159 Under the recovery scenario, WEEE becomes a significant resource for secondary raw  
1160 materials. Technological advancements in the sector improve the efficiency of WEEE treatment,  
1161 although the consumerism-driven demand for new electronics remains high.

- 1162 • Advanced technologies enable higher recovery rates of valuable materials from WEEE
- 1163 • Despite advancements in design for recyclability, WEEE generation remains high due to
- 1164 the consumer demand for new electronics
- 1165 • Standardised and segregated collection systems for WEEE are implemented, improving
- 1166 the supply of materials for recovery
- 1167 • Increased industry-government collaboration leads to further development in WEEE
- 1168 recovery technologies
- 1169 • Consumer behaviour remains a significant hurdle for more efficient WEEE management
- 1170 • Higher recycling rate — make full use of the disposed parts. For instance:

- 1171       – more automation of the dismantling and processing steps (e.g., AI)
- 1172       – recycling technologies improvements (e.g., small components recovery is also
- 1173       happening)
- 1174       – more effective collection infrastructure
- 1175       – financial support provided to recyclers/operators
- 1176       – bans on WEEE exports push for increased domestic recycling [45]
- 1177       • 'Design for recovery' principle — Ecodesign mandates changes in weight and composition
- 1178       of EEE so complexity and the type of materials used
- 1179       • Higher public awareness and participation on WEEE issue and management
- 1180       • Higher compliance from the public, the producers and the businesses
- 1181       • Strong regulations and monitoring are in place with higher collection and recycling targets
- 1182       which are set and implemented and fines are set to those who fail to achieve the targets
- 1183       • Focus given more to the EoL management of WEEE

#### 1184       **Mining waste (MIN)**

1185       Under the recovery scenario, technological advancements enable the extraction of residual  
1186       valuable materials from mining waste, transforming it into a valuable resource.

- 1187       • Technological advancements facilitate the extraction of valuable materials from mining
- 1188       waste.
- 1189       • Despite progress in recovery technologies, primary extraction remains the dominant
- 1190       source of raw materials due to high consumer demand.
- 1191       • Government and industry collaboration support the development of technologies for
- 1192       the recovery of materials from mining waste.
- 1193       • Increased traceability and management of mining waste through digitalisation.
- 1194       • Mining waste remains a significant environmental challenge.

### 1195 **CDW (Construction and Demolition Waste) [43]**

1196 Under the recovery scenario, Construction and Demolition Waste (CDW) becomes an  
 1197 important resource for secondary raw materials, though mostly base metals and aggregates.  
 1198 Despite some progress in eco-design and material efficiency, the construction industry contin-  
 1199 ues to generate significant amounts of waste or 'downcycled' materials.

- 1200 • Advanced recovery technologies allow for higher recovery rates of valuable materials  
 1201 from CDW.
- 1202 • Despite improvements in design and material efficiency, CDW generation remains high  
 1203 due to the construction demand.
- 1204 • Eliminating the disposal of any avoidable CDW, through the implementation and expan-  
 1205 sion of incentives, and regulatory measures.
- 1206 • The focus of this scenario is to significantly reduce the amount of CDW that ends up in  
 1207 treatment plants without any useful applications, e.g., landfilling, incineration, and land  
 1208 spreading.
- 1209 • This scenario is characterized by a high recovery rate, achieved via:
  - 1210 – increased investment and enhanced regulatory system in waste management
  - 1211 – leading to more waste recovery infrastructure
  - 1212 – widespread application of selective demolition and on-site waste sorting
- 1213 .
- 1214 • Recovery of minerals is intensified with a stronger focus on closed-loop recycling (e.g.,  
 1215 concrete waste is used as aggregates in concrete; recovery of cement is explored).
- 1216 • Recovery of other materials like glass, plastics, and wood is also intensified.
- 1217 • Better separation of waste at source leads to a higher quality of secondary raw materials.
- 1218 • Improved recycling of wind turbine blades is notable, especially regarding plastics; per-  
 1219 manent magnets are recycled at a functional level.

### 1220 SLASH (Slags and Ashes)

1221 In the recovery scenario, SLASH are recognized as a potential resource for secondary raw  
1222 materials. Advances in recovery technologies enable the extraction of valuable metals from  
1223 SLASH, however, the total volume of CRMs recovered from this material remains low, except  
1224 in cases of supply constraint.

- 1225 • Advanced recovery technologies allow for the extraction of valuable metals and minerals  
1226 from SLASH.
- 1227 • Despite improvements in energy production, SLASH generation remains significant due  
1228 to the continued reliance on traditional energy sources.
- 1229 • New regulations incentivize the recovery and reuse of materials from SLASH.
- 1230 • Digital solutions enhance the traceability and management of SLASH.
- 1231 • SLASH remains a significant environmental challenge due to the volume generated.
- 1232 • Transferring down-cycling to recycling or even upcycling.
- 1233 • Recycling technology improvements (e.g., cement additives using biomass ash is under  
1234 investigation)
- 1235 • More functional collection infrastructure.
- 1236 • Financial support provided to recyclers/operators.
- 1237 • Introduction of SRM/CRM recovery targets. For example, recovery of P from biomass  
1238 ash for fertilizer. Recovery of Zn and Pb from Zn and Pb smelter slag.
- 1239 • Higher awareness and participation of relevant sectors on SLASH issue and management.
- 1240 • Strong regulations and monitoring are in place with higher collection and recycling targets.

## 2.3 Scenario 3: Circularity

### 2.3.1 Storyline narrative

In this scenario, we move in the direction of the maximum achievable state of material efficiency as government policy, private innovation and social changes are rapidly driving the transition toward a circular economy. The emphasis here rests heavily on re-X strategies that are implemented in the design phase of products (e.g., repairability and re-manufacturability) and that are actualised by changes in consumer behaviour (e.g. reduction, refusal, engagement in the 'sharing-economy' and curtailment of the 'throw-away' mindset). Further, being enabled by the widespread adoption of 'circular design' principles and improvements in information transparency (e.g., waste tracking and digital product passports) the system for the treatment of post-consumer waste can divert a significant amount of their inflows (to, for example, re-use and re-manufacture) with the residual fraction being readily segregated into purer, more efficiently recoverable, material streams. This scenario envisions a future where government policies are in synergy with private sector innovation and societal changes, driving a wholesale transition towards a circular economy. Unlike the recovery scenario, where the focus is on the end-of-life recovery of materials, this scenario emphasises minimising waste at all stages, starting from the design phase itself.

The emphasis is on re-X strategies that are integrated right from the product design stage. This includes repairability, where products are designed to be easily fixed rather than replaced; and re-manufacturability, where products or their components are designed to be restored to their original state, extending their lifespan and reducing the need for new resources. This scenario calls for a drastic change in consumer behaviour, where reduction in consumption and waste, refusal of non-sustainable options, and active participation in the 'sharing economy' become the norm rather than the exception.

In the circularity scenario, the widespread adoption of 'circular design' principles becomes a cornerstone of production. In a circular design approach, products are designed and produced in a way that considers their entire lifecycle, including eventual disassembly and reuse. This

means that every component of the product can either be biologically broken down without any harm to the environment or technically reprocessed into new products, creating a closed loop of materials.

Additionally, this scenario envisions an improvement in transparency, with measures such as waste tracking and digital product passports becoming standard. Waste tracking allows for efficient management of waste flows, aiding in effective resource planning, while digital product passports provide information about a product's composition and how it can be properly disassembled, reused, or recycled.

### 2.3.2 Waste stream specific scenario impacts

#### BATT (Battery waste) [11, 12, 25, 26]

In the circularity scenario, battery waste treatment undergoes a massive transformation. The shift towards electric vehicles and renewable energy storage significantly increases the quantity of end-of-life batteries. However, thanks to new regulations, technological advancements, and business models, the majority of battery components are recycled or reused.

- Massive increase in end-of-life batteries due to the shift to electric vehicles and renewable energy storage.
- New regulations incentivise battery manufacturers to design for recycling.
- Battery recycling technologies improve, enabling higher recovery rates of valuable metals.
- Standardised collection systems for battery waste are established, improving the efficiency of the recycling process.
- Service-based business models like leasing ensure manufacturers retain ownership of the batteries, promoting circularity.
- Greater transparency through digital product passports aids in effective battery waste management.

- 1292 • Battery passport and publicly accessible Information from new Battery Regulation (SoH,  
1293 SoC, Predicted lifetime/warranty, etc.) given by the economic operator that places the  
1294 battery on the market enables high re-use rates.
- 1295 • Increased repairability/modularity.
- 1296 • Reduced demand from 'sharing economy' and more 'sustainable' transport choices.
- 1297 • New emerging technologies more suited for reuse/repair.
- 1298 • Ambitious targets set by business and public policy.

#### 1299 **ELV (End-of-Life Vehicles) [12, 27, 35, 36, 37]**

1300 For End-of-Life Vehicles (ELVs), the circular economy model affects the way vehicles  
1301 are designed, used, and discarded. Emphasising extended vehicle life through repair and  
1302 remanufacturing, this scenario also focusses on the recovery of materials from vehicles at the  
1303 end of their life [27, 35, 36, 37].

- 1304 • Vehicle design shifts towards repairability, upgradability, and recyclability, increasing the  
1305 lifespan of vehicles.
- 1306 • Standardised systems for ELV collection are established, ensuring efficient waste man-  
1307 agement.
- 1308 • Innovative technologies enable higher recovery rates of metals and other valuable mate-  
1309 rials from ELVs.
- 1310 • Service-based models like vehicle leasing and sharing could reduce the total number of  
1311 vehicles produced.
- 1312 • Digital product passports provide information about vehicle components, aiding in effec-  
1313 tive recycling or reuse.
- 1314 • Focus on managing use-phase of vehicles.
- 1315 • Circular strategies take place before material recovery so that material recovery is "de-  
1316 layed".

- 1317 • Information available to enable these strategies.
- 1318 • EU vehicles policy have implications for materials in vehicles, such as light weighting and
- 1319 down sizing
  - 1320 – Increase in average occupancy and average vehicle-kilometres per trip.
  - 1321 – Decrease in average lifetime (in terms of years): As the utilisation factor increases.
- 1322 • Increase in circular strategies due to an increase in participation from the public and
- 1323 businesses, i.e., target-based incentives with strong regulations and monitoring.

1324 **WEEE (Waste Electrical and Electronic Equipment) [38, 39, 40, 41, 42]**

1325 In the circularity scenario, WEEE becomes a valuable resource instead of a disposal challenge.

1326 Thanks to product design changes and the application of advanced recovery technologies, a

1327 significant percentage of the materials in WEEE is reclaimed and fed back into the production

1328 cycle.

- 1329 • Electronic products are designed for longevity, repairability, upgradability, and recyclabil-
- 1330 ity.
- 1331 • Advanced technologies enable higher recovery rates of precious metals from WEEE.
- 1332 • Collection systems for WEEE are improved, ensuring a steady supply of materials for
- 1333 recycling.
- 1334 • Digitalisation and data use enhance traceability and efficiency in WEEE management.
- 1335 • Service-based models for electronics promote the use of products as a service rather
- 1336 than ownership, reducing WEEE generation [19].
- 1337 • Increased durability and lifespans.
- 1338 • Increased repairability.
- 1339 • More sharing and product-service systems, corresponding to a reduction in the lifetime
- 1340 (for some equipment).

- 1341 • More reuse practices (expanded second-hand market).
- 1342 • Less hoarding.
- 1343 • Higher formal collection and recycling rate.
- 1344 • Focus given more to the production and use phase rather than the EoL (End-of-Life).
- 1345 • 'Design for circularity' principle: Ecodesign mandates repairability, durability, no obsoles-
- 1346 cence, modularity, and that continual software upgrades are possible [46, 47].
- 1347 • Electronically compatible chargers and battery packs are able to be used across different
- 1348 products .
- 1349 • The above also means that chargers and batteries are not integrated into the product,
- 1350 and that the product is designed to be easily disassembled.
- 1351 • Strong regulations and monitoring are in place with higher reuse and circular targets,
- 1352 which are set and implemented, and fines are imposed on the member states that fail to
- 1353 achieve the targets.
- 1354 • Support and development of circular strategies infrastructure (e.g., easy information
- 1355 access for repairability, repairing shops, accessibility to spare components on the market,
- 1356 etc.).
- 1357 • Greater use of connected products, smart technologies, and the IoT. Used to monitor
- 1358 and diagnose product performance in situ which, can extend product and component
- 1359 life.

#### 1360 **Mining waste (MIN)**

1361 In this scenario, the impact on mining waste is two-fold. Firstly, the need for primary mining  
1362 is reduced due to efficient resource use and high recovery rates of materials. Secondly, mining  
1363 waste itself is treated as a valuable resource, with advanced technologies being used to extract  
1364 residual valuable materials.

- 1365 • Decrease in primary mining reduces the generation of mining waste.

- 1366 • Advanced technologies are employed to extract valuable materials from mining waste.
- 1367 • Policies and regulations incentivise the reuse of mining waste in various applications.
- 1368 • Digital solutions improve tracking and management of mining waste.
- 1369 • Collaboration between stakeholders promotes circular practices in the mining industry.

#### 1370 **CDW (Construction and Demolition Waste) [43]**

1371 Construction and Demolition Waste (CDW) is another sector that sees significant improve-  
1372 ment in the circularity scenario. Emphasising design for disassembly and the use of recyclable  
1373 materials, this scenario drastically reduces the generation of CDW and promotes the recovery  
1374 of valuable materials from the waste stream.

- 1375 • Buildings are designed for disassembly, increasing the lifespan of materials and reducing  
1376 CDW.
- 1377 • Recycling technologies for CDW improve, allowing higher recovery rates of materials.
- 1378 • Policies and regulations incentivise the use of recycled materials in construction.
- 1379 • Standardised systems for CDW collection and separation are established.
- 1380 • Digital tools like building information modelling (BIM) improve resource management in  
1381 construction.
- 1382 • This scenario envisions a almost closed-loop system where CDW is considered a resource,  
1383 with an emphasis on minimising waste generation and maximising resource efficiency in  
1384 recovery.
- 1385 • Waste reduction is prioritized through the implementation of eco-designs, including  
1386 designing out waste (DOW), lightweight design (LWD), and design for dismantling (DFD).
- 1387 • Reuse and repair standards and networks are established to boost the reuse of end-of-life  
1388 building components and equipment.
- 1389 • If reuse is no longer possible, waste is recycled through high-efficiency recycling facilities  
1390 rather than down-cycled or used for energy recovery.

- 1391 • This scenario is characterized by meeting all material needs through recovery (including  
1392 mineral wastes from other industries) with high material efficiency achieved through the  
1393 development of new business models, advanced designs and recycling technologies,  
1394 strict waste management regulations, and innovative products and services.
- 1395 • Plausible target: Achieving a 100% recovery rate of avoidable CDW by 2050, with a  
1396 recycling rate accounting for 30% and component reuse accounting for 20%. Raw  
1397 material consumption should be reduced by 50% compared to the 2020 level.
- 1398 • Example of treatment technological development: Waste concrete is primarily recy-  
1399 cled through an innovative mobile dry process. Biodiesel-based thermal treatment is  
1400 applied to further pyrolyze the fine aggregate to recover cement. Lightweight design is  
1401 implemented to reduce concrete use.

#### 1402 **SLASH (Slags and Ashes)**

1403 In the circularity scenario, the approach to SLASH dramatically changes. Instead of being  
1404 treated as waste, SLASH is seen as a valuable secondary raw material. Advances in technology  
1405 allow for the extraction of valuable metals and minerals from SLASH, which then re-enter the  
1406 material cycle.

- 1407 • A shift in perception treats SLASH as a valuable resource instead of waste.
- 1408 • Advanced technologies enable the extraction of valuable metals and minerals from  
1409 SLASH.
- 1410 • New regulations incentivise the use of SLASH in various applications, such as in the  
1411 construction industry.
- 1412 • Digital solutions enhance the tracking and management of SLASH.
- 1413 • Collaboration between industries utilises SLASH in new and innovative ways.
- 1414 • Reduce the generation of SLASH by increasing the efficiency of the manufacturing side.  
1415 For example, developing higher efficient production of metals and reducing by-products  
1416 such as smelter slag. For ash from the incineration of solid biomass, maximizing the use

- 1417 of biomass by setting proper temperature, time, and furnace conditions to reduce ash  
1418 contents and improve the efficiency of power and heat generation. For ash, developing  
1419 other renewable technologies from bioenergy to reduce the incineration of solid biomass,  
1420 e.g., biogas.
- 1421 • Reduce the generation of SLASH by increasing the proportion of higher calorific waste  
1422 and decreasing lower calorific waste, e.g., MSW (Municipal Solid Waste).
  - 1423 • Developing domestic feedstock supply for bioenergy or metal production to reduce the  
1424 cost of transportation and others.
  - 1425 • Higher formal collection and recycling rate compared to BAU, but lower compared to  
1426 the Recovery scenario.

## 1427 Chapter 3

## 1428 Quantification

To be completed in the next stages of the project.

## 1430 **Chapter 4**

## 1431 **References**

## Chapter 4. References

## 1581 **Chapter 5**

## 1582 **Appendices**

## 1583 5.1 Terminology

1584 The following is a suggested terminology for use in our discussions and reports related to  
1585 scenarios.

1586 This glossary is modelled on that used by [\[22\]](#). Some additional definitions were sourced  
1587 from [\[48\]](#).

Table 5.1: Terminology

Term	Definition	Level/Context	Also called	Source
Normative scenario	Goal-oriented scenario: identify decisions and investments that must be made to achieve desired future outcomes. Example: Constraining cumulative emissions	Scenario type	Backcasting	Skea
Exploratory scenario	Exploration of plausible alternative developments to test whether decision-making is robust against different outcomes. Generally, involving a qualitative storyline about a possible future, complemented by quantitative analysis. Example: Socio-economic scenarios	Scenario type	Plausible scenarios	Skea
Outlook	To provide a most likely estimate of future trends as a guide for decision-making	Scenario type	Forecast, projection	Skea
Scenario characteristics	A combination of the vague attributes that make up the qualitative storyline for a scenario. For example, in WEC (2019) the scenario titled Modern Jazz is described as: “A market-led, digitally disrupted world with faster-paced and more uneven economic growth. Recent signals suggest that this entrepreneurial future might accelerate clean energy access on both global and local scales, whilst presenting new systems integration, cyber security and data privacy challenges”	Scenario description	Qualitative storyline descriptors	Skea
Scenario scale	Description of the spatial extent or temporal extent of a scenario. For us, mostly EU toward 2050.	Scenario component		UniArizona
Scenario dimensions	Uncertainties around which scenarios are constructed, represented as axes in some methods. In our case they might end up being, level of circularity, free-trade/autarky, progress in energy transition	Scenario component		UniArizona
Scenario literature	Journal articles, grey literature, etc., from which data is sourced that can be used to justify decisions in scenario development	Scenario component		

Continued on next page

Table 5.1 — Continued from previous page

Term	Definition	Level/Context	Also called	Source
Scenario logics	Methods for structuring the relationships between different drivers and assumptions in scenarios	Scenario component		Rowland et al. 2014 reported in UniArizona
Time horizon	End date of the scenario's forecast	Scenario attribute		Skea
Snapshot	The position of scenario/s at a particular point of time	Scenario attribute		Skea
Storyline and simulation	Combination of qualitative narrative development and quantitative modelling	Scenario component		Mahmoud et al. 2009, Wollenberg et al. 2000 reported in UniArizona
Marker scenario	Generally, a widely accepted scenario which can be used a guide or to provide background information. E.g., SSP1-5, and the GEC models from the IEA. If applicable, these can be extended upon or combined to help build our models.	Scenario description	Basis scenario	Skea
SSP	Shared Social Pathways. They “describe plausible major global developments that together would lead in the future to different challenges for mitigation and adaptation to climate change. The SSPs are based on five narratives describing alternative socio-economic developments, including sustainable development, regional rivalry, inequality, fossil-fuelled development, and middle-of-the-road development. The long-term demographic and economic projections of the SSPs depict a wide uncertainty range consistent with the scenario literature.”	Marker scenario examples		PBL

Continued on next page

Table 5.1 — Continued from previous page

Term	Definition	Level/Context	Also called	Source
IEA and GEC	Global Energy and Climate Model of the International Energy Agency. Used to create their forecasts: Net Zero Emissions (NZE), Announced Pledges Scenario (APS), and Stated Policies Scenario (STEPS)	Marker scenario examples		IEA
Drivers	Underlying causes of system change that are external from the system of analysis. They come from higher scales and are not affected by what happens within the system.	Scenario component	Factors	Walker et al. 2012, reported in UniArizona
Factors	Causes of system change that are internal from the system of analysis. Can be (hopefully) quantified, or at least estimated	Scenario component (internal)		
Factor variables	Discrete elements which are subject to change and have effects on one or more factors	Factor component		
Factor parameters	Discrete elements which are NOT subject to change (possibly based on assumptions and simplifications) and have effects on one or more factors	Factor component		
Trends	An inclination in a particular direction	Attribute of drivers or factors	System development	
Likelihood	The likelihood of an occurrence, an outcome, or a result, where this can be estimated probabilistically.	Attribute of drivers or factors	Probability	Rowland et al. 2014, IPCC standard

## 1588 **5.2 Scenario development methods**

1589 The following table provides an overview of the methods and tools considered, along with a  
1590 brief description of each and its relevance to the specific context and objectives of the FutuRaM  
1591 scenario development process.

Table 5.2: Scenario development methods

Method	Description	Key characteristics	Limitations	Application
Delphi	Structured expert consultation to gather and distil knowledge and judgments	Iterative rounds of surveys/questionnaires, Expert consensus building	Time-consuming process, May be influenced by dominant opinions or group dynamics	Policy development, Technology foresight, Long-term planning
MCA	Decision-support technique to evaluate and rank scenarios based on criteria	Consideration of multiple dimensions in quantifying qualitative factors	Policy assessment, Project evaluation, Strategic planning	
Forecasting	Use of historical data and statistical methods to predict future trends	Reliance on quantitative models, Time series analysis	Assumption of future patterns based on past data, Sensitivity to data quality and accuracy	Economic forecasting, Demand/supply projections, Financial planning
Backcasting	Working backward from a desired future vision to identify necessary steps	Focus on desired outcomes and future targets, Identification of necessary actions	Uncertainty in future outcomes, Difficulty in determining feasible pathways	Sustainable development planning, Policy design, Long-term goal setting
Scenario Planning	Development of multiple future scenarios to understand the range of possibilities	Identification of key drivers and uncertainties, Narrative construction for each scenario	Subjectivity in scenario construction, Lack of predictive accuracy	Strategic management, Risk assessment, Policy analysis
Morphological Analysis	Exploration of different combinations of variables/factors	Matrix-based exploration of variables and combinations	Complexity in analysing a large number of variables and combinations	Technology assessment, Innovation analysis, System design

Continued on next page

Table 5.2 – Continued from previous page

Method	Description	Key characteristics	Limitations	Application
Cross-Impact Analysis	Analysis of interdependencies and interactions between variables/factors	Identification of relationships and cross-impacts	Assumptions about causal relationships, Difficulty in capturing complex dynamics	Policy analysis, Risk assessment, System modelling
Morphological Box	Systematic exploration of the potential combinations of different components	Identification of component options and combinations	Complexity in analysing a large number of components and combinations	Technology assessment, Innovation analysis, Decision-making
Gausemeier approach	Scenario development method involving the identification of future developments, evaluation of influencing factors, and determination of desired and undesired developments	Systematic analysis of future developments and factors	Relies on expert judgment and subjective assessments	Strategic planning, Innovation management
Schwartz' 8-Step Scenario Model	Scenario building model consisting of eight steps: identify the focal issue, determine the key forces, construct the scenario framework, identify driving forces, assess the uncertainties, develop the scenarios, analyze the scenarios, and monitor and adjust the scenarios	Systematic progression through stages of scenario development	Requires detailed data and analysis	Strategic planning, Decision-making
Schoemaker's 10-Step Scenario Model	Scenario building model consisting of ten steps: identify the focal issue, determine the scope, identify the key driving forces, develop the scenarios, define the scenario logic, assess the scenarios, refine the scenarios, examine implications, formulate actions, and communicate results	Emphasis on thorough analysis and evaluation of scenarios	Can be time-consuming and resource-intensive	Strategic planning, Risk management

### 1592 **5.3 Marker scenario mapping**

1593 The following table presents an overview of the marker scenarios considered in the FutuRaM  
1594 project. The table is not intended to be exhaustive, but rather to provide an overview of the  
1595 different scenarios that have been developed in the field of waste management, resource  
1596 recovery, and circular economy.

Table 5.3: Overview of marker scenarios

Literature	Type	Waste stream	Temporal Coverage	Location	Number of scenarios	
The Shared Socioeconomic Pathways and their energy, land use, and greenhouse gas emissions implications: An overview	Academic	All (narratives)	Scenario to 2100	Global	5 SSPs	<a href="#">Link</a>
Environmental Impacts of Global Offshore Wind Energy Development until 2040	Academic	C&D	Scenario: 2019–2040	Global	4 (based on IEA)	<a href="#">Link</a>
Global greenhouse gas emissions from residential and commercial building materials and mitigation strategies to 2060	Academic	C&D	Scenario: 2020–2060	Global	2 (based on SSP2)	<a href="#">Link</a>
Modelling global material stocks and flows for residential and service sector buildings towards 2050	Academic	C&D	Scenario: 2020–2060	Global	1 (SSP2)	<a href="#">Link</a>
The evolution and future perspectives of energy intensity in the global building sector 1971–2060	Academic	C&D	Scenario: 2020–2060	Global	1 (SSP2)	<a href="#">Link</a>

1597    **5.4    Drivers and factors identified in the initial collection phase**

1598    The following table lists the elements that were identified in the initial phase of driver/factor  
1599    collection.

Table 5.4: Drivers and factors identified in the initial collection phase

Method	Description
Stricter environmental regulations	Increased regulations and policies aimed at reducing environmental impact
Inflation	Increase in the general price level of goods and services over time
Employment rates	Percentage of the working-age population that is employed
Exchange rates	Value of one currency relative to another currency
Interest rates	Cost of borrowing money or the return on investment
Gasoline price	Cost of gasoline for vehicles
Electricity price	Cost of electricity for consumers or businesses
Raw material prices	Prices of primary materials used in production processes
CO2 market	Trading system for carbon emissions permits or credits
Education level	Level of education attained by individuals or the overall population
Volunteering	Engagement in unpaid activities for the benefit of others
Transparency	Openness, accountability, and information accessibility
Compliance with rules	Adherence to regulations, guidelines, or standards
Cultural values / Consciousness	Beliefs, attitudes, and awareness of individuals and society
Accessibility	Ease of access to goods, services, or infrastructure
Land rights	Legal rights to ownership, use, or access to land
Work-life balance	Equilibrium between work and personal life
Urbanisation	Increase in the population living in urban areas
Water supply constraints	Limitations on the availability or access to freshwater resources
Increased intrinsic drive for env. protection	Growing internal motivation to protect and conserve the environment
NIMBY to projects	Not-In-My-Backyard opposition to the location of certain projects
Climate change impacts (flooding, etc.)	Consequences of climate change, such as increased flooding or extreme events
Climate change mitigation efforts	Actions taken to reduce greenhouse gas emissions and combat climate change
Redundancy	Availability of backup systems or alternative options
Material efficiency	Effective use and management of materials to minimize waste and loss
Energy efficiency of buildings	Performance and efficiency of energy consumption in buildings

Continued on next page

Table 5.4 – Continued from previous page

Driver/factor	Definition
Change of products in the scope WEEE directive	Inclusion or exclusion of certain products within the scope of the WEEE directive
GDP/PPP	Gross Domestic Product (GDP) adjusted for purchasing power parity (PPP)
Improved repairability	Enhanced ability to repair and maintain products or equipment
Target enforcement	Implementation and enforcement of specific targets or goals
Data protection	Safeguarding personal data and ensuring privacy
Infrastructure	Physical structures and facilities necessary for the functioning of society
Intellectual property issues	Legal rights and protections for intellectual creations and innovations
Population	Total number of people in a given area or region
Resource shortage	Insufficient availability or scarcity of natural resources
Treatment cost	Cost of waste treatment, disposal, or recycling processes
Digital product passports	Digital documentation providing information about a product's lifecycle
Obsolescence	State of being outdated or no longer in use or demand
Digitalization	Integration and adoption of digital technologies and processes
SRM prices	Prices of secondary raw materials or recycled materials
Product prices	Prices of goods or products in the market
Recyclability mandates	Requirements or regulations promoting the recyclability of products
Conflict in supply chain	Disputes or conflicts within the supply chain of raw materials or products
Obligatory recycling standards for treatment facilities	Mandatory standards for recycling processes in treatment facilities
Improved durability	Enhanced longevity and resistance of products or materials
Composition change	Alteration or modification of the composition of materials or products
Subsidies	Financial support or incentives provided by governments or organizations
Availability of recovery technologies	Existence and accessibility of technologies for material recovery
Taxation (raw materials, landfill)	Imposition of taxes on raw materials or landfill activities
Obligatory removal of CRMs from waste	Required removal or extraction of critical raw materials from waste streams
Corruption	Dishonest or unethical behaviour, typically involving misuse of power
Supply chain due diligence laws	Regulations or laws requiring companies to assess and manage supply chain risks

Continued on next page

Table 5.4 – Continued from previous page

Driver/factor	Definition
Improved recyclability	Increased ability of products or materials to be recycled or reused
Ecodesign	Designing products with consideration for their environmental impact
Trade barriers	Barriers or restrictions to international trade or commerce
Industrialization of Europe	Development and growth of industrial activities in European countries
Reduced consumerism	Shift towards decreased consumption and a more sustainable lifestyle
Accessibility/Infrastructure	Availability and adequacy of infrastructure to support accessibility
New mines in rich EU countries?	Establishment of new mines in economically prosperous European countries
Miniaturization	Process of making products or components smaller and more compact
Sharing economy	Economic system based on sharing resources and services
Repairability mandates	Requirements or regulations promoting the repairability of products
Renewable energy targets	Set goals or objectives for increasing the use of renewable energy sources

## 1600 **5.5 Drivers and factors identified in the screening phase**

1601 The following table lists the scenario elements that were identified in the screening phase of  
1602 driver/factor collection.

Table 5.5: List of drivers and factors identified in the screening phase

Domain	Driver/factor	Definition	BAU	REC	CIR
Technical	Recovery technology	Technologies and processes for recovering materials from waste	I	III	III
Technical	Product technology	Changes in product function or composition that lead to changes in waste stream composition and quantity	I	III	III
Economic	Market saturation	Level of saturation reached in the market for certain products or services			
Technical	Digitisation	Adoption and integration of digital technologies	I	I	I
Technical	Integration of SRM system across EU	Integration of a Secondary Raw Materials (SRM) system across the European Union	I	III	III
Legal/Political	Stricter environmental regulations	Implementation of more stringent rules and regulations for environmental protection	I	III	III
Legal/Political	Product information transparency	Provision of transparent product information to consumers, manufacturers, importers, repairers, recyclers, or national authorities	I	III	III
Legal/Political	Ecodesign/re-X mandates	Establishment of ecodesign requirements for specific product groups to improve circularity, energy performance, and other environmental sustainability aspects	I	II	III
Legal/Political	Supply chain due diligence laws: implementation/enforcement	Implementation and enforcement of laws requiring companies to address negative human rights and environmental impacts in their value chains	I	II	III
Legal/Political	Governance: corruption vs compliance	Contrasting levels of corruption and compliance within governance systems			
Legal/Political	Progress toward renewable energy targets	Progress made in achieving renewable energy targets		II	III
Legal/Political	Subsidies/taxation to promote circularity	Provision of subsidies or implementation of taxation policies to incentivize circularity		I	II
Legal/Political	International trade and co-operation (vs. autarky)	Level of international trade and cooperation versus self-sufficiency			
Economic	CO2 market price	Price of carbon dioxide (CO2) emissions in carbon markets			
Economic	Energy prices	Prices of energy resources			
Economic	Economic growth	Rate of economic growth	I	I	
Economic	Re-industrialisation of EU	Process of revitalizing industrial activities in the European Union			
Economic	Raw material vs SRM prices	Price comparison between raw materials and Secondary Raw Materials (SRMs)			
Environmental	Climate change impacts (flooding, etc.)	Impacts of climate change such as flooding and other related events			

Continued on next page

Table 5.5 — Continued from previous page

Domain	Driver/factor	Definition	BAU	REC	CIR
Environmental	Climate change mitigation efforts	Efforts made to mitigate the effects of climate change			
Environmental	Increased drive for env. protection	Growing motivation and drive to protect the environment	I	III	III
Environmental	Resource shortage	Shortage of natural resources	II	I	
Social	NIMBY to projects	Opposition of local communities to the location of new projects, such as mining, in their vicinity			
Social	Population	Size and growth of the population			
Social	Urbanisation	Rate of urban population growth			
Social	Hoarding	The act of stockpiling and keeping excessive amounts of products		II	III
Social	Participation in re-X activities	Involvement in activities related to the "re-" concepts, including refusing, reducing, repairing, and reusing products	I	II	III
