

# Futu RaM

Future availability  
of secondary  
raw materials

## Work Package 2

Future recovery of secondary raw materials

Scenario Development

**DRAFT REPORT**

**VERSION: 2.1**

Stewart Charles McDowall

October 19, 2023

THIS IS A DRAFT REPORT

please submit comments and corrections  
to [s.c.mcdowall@cml.leidenuniv.nl](mailto:s.c.mcdowall@cml.leidenuniv.nl) or directly:

- In a CSV file with the format: 'line number, comment, name, reference' (if reference is applicable, please provide the DOI or BibTeX).
- FutuRaM members can do this directly via [this link](#).
- Or directly as a pull request to the  $\text{\LaTeX}$  source files on the [WP2 GitHub repository](#).

## TODO

### TO DO

- Add more references, especially for the targets, regulations, and projections.
- Waste stream groups to re-check the sections related to their waste streams.
- Discuss main points raised by reviewers:
  - Consideration of possible resource constraints in the scenarios.
    - \* We suggest covering this in sensitivity analysis and optimisation playground.
  - How to transfer general targets to individual waste streams?
    - \* We would need a set of constraints for each of the recovery flows and processes, as well as the individual waste flows (by code) in each WS, to backcast this.
  - Economic Considerations.
    - \* Addressing the fact that industrial ecology scenarios often exclude or have a limited view of economic factors.
  - Geopolitical Considerations.
    - \* How geopolitical changes and directions are being factored into the scenarios.
  - Scenario Relation with UNFC.
    - \* Addressing the relevance of the scenarios with the United Nations Framework Classification (UNFC).
  - E-mobility.
    - \* Do we hold it level across the scenarios?
    - \* In Germany, the Autolobby & Deutschland GmBh have killed the ICE ban...

# 1 I. Preface

2 The **FutuRaM project** aims to quantify the current and future availability of secondary raw  
3 materials (SRM), focusing on critical raw materials (CRMs) [**graedel2015materials**]. This study  
4 is concerned with six waste streams in the EU member states, as well as Iceland, Norway,  
5 Switzerland, and the United Kingdom (EU27+4). In this report, the EU27+4 will henceforth be  
6 referred to as the EU, unless specified otherwise.

7 **The waste streams covered in FutuRaM are:**

- 8 • waste electrical and electronic equipment (WEEE)
- 9 • waste batteries (BAT)
- 10 • end-of-life vehicles (ELV)
- 11 • mining waste (MIN)
- 12 • slags and ashes (SLASH)
- 13 • construction and demolition waste (CDW)

14 Work package two (WP2) is conducting foresight studies for materials that are either classi-  
15 fied as critical to the EU economy or are significant due to factors such as their large volumes,  
16 commercial importance, and environmental impacts [**eu2023crmact**, **eu2023crmstudy**, **eu2023crmqna**,  
17 **graedel2015materials**]. WP2 is tasked with developing a set of coherent scenarios for material  
18 use and waste/recovery over time across various sectors in the EU. This report describes the  
19 three distinct scenarios and the process by which they were developed.

20 **The scenarios that have been developed in FutuRaM are:**

- 21 • Business-as-usual (BAU)
- 22 • Recovery (REC)
- 23 • Circularity (CIR)

## 24 II. Executive Summary

25 This report presents the first phase of the scenario development process — the storyline  
26 narrative phase. Three distinct future scenarios have been drafted up to the year 2050, Business  
27 as usual, Recovery and Circularity. The scenarios are designed to be internally consistent  
28 and to provide an overview of the potential future landscape of waste management and  
29 SRM recovery within the EU. The scenario development process employs a methodology  
30 that integrates both forecasting and backcasting techniques to construct a comprehensive,  
31 future-facing knowledge base that can aid fact-based decision-making [dreborg1996essence,  
32 boerjeson2005, amer2013, sardesai2021, lloyd2014objectivity, ardente2014].

### 33 Scenario 1: Business as Usual (BAU)

34 The BAU scenario extends the current situation into the future with limited deviation from  
35 existing patterns. Utilising forecasting techniques, it assesses a potential future where there are  
36 minor advancements in resource efficiency, recovery technology, and the energy transition,  
37 but in which primary extraction of raw materials remains the dominant practice.

### 38 Scenario 2: Recovery (REC)

39 The Recovery scenario envisions a future that employs sophisticated technology to dramatically  
40 enhance SRM recovery from waste streams. It presents a future where the EU successfully  
41 meets its recycling and recovery targets through an effective waste management system and  
42 circular design principles [halleux2021batt, helander2023battelv]. The scenario envisions an  
43 increased recovery rate of SRMs, extensive use of digitalisation and automation in recycling  
44 processes, and the implementation of new (or enforcement of existing) waste regulations in  
45 alignment with EU targets.

### 46 Scenario 3: Circularity (CIR)

47 The Circularity scenario encapsulates the fullest possible realisation of a circular economy,  
48 extending beyond end-of-life recovery of materials to minimising waste at all stages of pro-  
49 duction and consumption. It envisions a future where the EU's targets for recycling, recovery,  
50 and circularity are met through extensive stakeholder collaboration, the emergence of new  
51 business models, and increased use of renewable energy and circular economy technolo-

gies [eu2020circ, kirchherr2017circ, domenech2019transition].

In subsequent phases of the scenario development process, future product composition and recovery technology will be examined, scenario elements will be quantified, and all scenario data will be integrated and coupled with the quantitative models for waste generation and SRM recovery.

Through the development of these scenarios, the FutuRaM project aims to provide a nuanced understanding of the potential future waste management and resource recovery landscape within the EU. This approach offers insights into key drivers, uncertainties, and the potential impacts of policy interventions and technological advancements. By aligning SRM recovery projects more closely with the United Nations Framework Classification for Resources (UNFC) [unfc2023], the project aims to enable the commercial exploitation of SRMs and CRMs by manufacturers, recyclers, and investors. Ultimately, the comprehensive knowledge base developed through this process is designed to support and inform the decision-making processes of policymakers and governmental authorities.

## 125 VI. Summary of scenario storylines

### 126 Scenario I: Business-as-usual (BAU)

127 See section 2.1 for the full scenario description and waste-stream-specific scenario impact  
128 narratives.

129 This scenario envisions the future based on the current situation, extending to 2050 with  
130 very little deviation from present consumption patterns and without substantial development  
131 of the secondary raw material (SRM) recovery system. While there may be advances in some  
132 areas such as resource efficiency, recovery technology, and the energy transition, substantial  
133 modifications remain hindered by economic, social, and political constraints. The extraction  
134 of primary raw materials continues to be the predominant source utilised to satisfy the EU's  
135 growing SRM demand.

136 In the Business as usual (linear economy) scenario, the following are key characteristics:

- 137 • A forecasting model is used to predict the future based on the current situation and the  
138 development of existing trends.
- 139 • EU targets including those for eco-design, recycling and recovery are not met, and the  
140 current linear model largely persists.
- 141 • Material demand remains coupled with economic growth, perpetuating a trend of in-  
142 creasing consumption.
- 143 • Primary mining and extraction persist as the leading sources of raw materials, underlining  
144 the dependency on traditional extraction methods.
- 145 • Recycling and recovery rates continue to lag, leading to increased production of SRM-  
146 containing waste that signals missed opportunities for resource reuse.
- 147 • The EU's dependency on imports of SRMs escalates, heightening the risk of supply  
148 disruptions [iea2023].

- 149 • Investment in new SRM recovery technologies remains minimal, stifling innovation and  
150 advancements in this field.
- 151 • The industrial focus remains on cost-effective material production and use, disregarding  
152 the long-term sustainability aspect.
- 153 • Material scarcity and price fluctuations pose potential risks to the EU industry, highlighting  
154 the vulnerability of this business model [mancini2013supplysecurity].
- 155 • Without any significant updates to environmental regulations, the negative impacts on  
156 ecosystems and biodiversity intensify.
- 157 • Mining activity in the EU remains limited and concentrated in only a few member states.  
158 Current exploration projects (e.g., for Lithium in PT, FR, UK and rare earths in SE) are not  
159 realised.
- 160 • The transitions to renewable energy and e-mobility continue at their current pace.

## 161 **Scenario II: Recovery**

162 See section 2.2 for the full scenario description and the waste-stream-specific scenario impact  
163 narratives.

164 In the recovery scenario, the central emphasis is on harnessing sophisticated technologies  
165 to salvage SRMs from waste streams at the end of their lifecycle. While there are noticeable  
166 strides towards the incorporation of 'circular design' principles and re-X strategies (which focus  
167 on reducing, reusing, recycling, repairing, and refurbishing), material demand increases similarly  
168 to the BAU scenario. This is, however, mitigated to some extent by the implementation of a  
169 comprehensive material recovery system.

170 **Key characteristics of this technology-promoted recovery scenario include:**

- 171 • This scenario uses a combination of forecasting and backcasting methods to envision  
172 the future.

- 173 • The backcasting method is used for scenario factors that are covered by governmental  
174 targets, starting with the desired outcome and working backwards to the present.
- 175 • The forecasting method is used for scenario factors that are not covered by governmental  
176 targets, starting with the current situation and extending to the future.
- 177 • EU targets for recycling and recovery are met, due to the EU's waste management system  
178 becoming more expansive, efficient and effective.
- 179 • Technological innovation drives increased recovery rates of SRMs, enabling the more  
180 efficient use of waste.
- 181 • Digitalisation and automation are more extensively used in recycling processes, leading  
182 to enhanced productivity and efficiency.
- 183 • Business models like leasing and take-back schemes emerge, altering traditional con-  
184 sumption patterns (here, the focus is on take-back for recycling).
- 185 • Ecodesign mandates are implemented, again, here, with a focus on end-of-life recovery.
- 186 • There is greater exploration and exploitation of alternative sources such as urban mining,  
187 waste streams, and tailings, presenting novel opportunities for resource acquisition.
- 188 • New waste regulations and guidelines for SRM recovery are implemented, enforcing  
189 better management and extraction of SRMs.
- 190 • Investment in research and development for SRM recovery technologies experiences an  
191 upswing, promoting continuous innovation in this field.
- 192 • Closer collaboration and information sharing between industry and government insti-  
193 tutions (e.g., waste tracking and digital product passports) streamline processes and  
194 expedite decision-making.
- 195 • New jobs are created in the recycling and recovery sector, offering economic benefits  
196 and improving overall employment rates.
- 197 • SRM production and use become more efficient and cost-effective, fostering economic  
198 sustainability.

## 199 **Scenario III: Circularity**

200 See section 2.3 for the full scenario description and the waste-stream-specific scenario impact  
201 narratives.

202 In this scenario, we move in the direction of the maximum achievable state of material  
203 efficiency as government policy, private innovation and social changes are rapidly driving the  
204 transition toward a circular economy. The emphasis here rests heavily on re-X strategies that  
205 are implemented in the design phase of products (e.g., repairability and re-manufacturability)  
206 and that are actualised by changes in consumer behaviour (e.g reduction, refusal, engagement  
207 in the 'sharing economy' and curtailment of the 'throw-away' mindset). Further, being enabled  
208 by the widespread adoption of 'circular design' principles and improvements in information  
209 transparency (e.g., waste tracking and digital product passports) the system for the treatment  
210 of post-consumer waste can divert a significant amount of their inflows (to, for example, re-  
211 use and re-manufacture) with the residual fraction being readily segregated into purer, more  
212 efficiently recoverable, material streams. This scenario envisions a future where government  
213 policies are in synergy with private sector innovation and societal changes, driving a wholesale  
214 transition towards a circular economy. Unlike the recovery scenario, where the focus is on  
215 the end-of-life recovery of materials, this scenario emphasises minimising waste at all stages,  
216 starting from the design phase itself.

217 **The circular economy scenario is characterised by the following:**

- 218 • This scenario uses a combination of forecasting and backcasting methods to envision  
219 the future.
- 220 • The backcasting method is used for scenario factors that are covered by governmental  
221 targets, starting with the desired outcome and working backwards to the present.
- 222 • The forecasting method is used for scenario factors that are not covered by governmental  
223 targets, starting with the current situation and extending to the future.
- 224 • EU targets for recycling and recovery are met, as are those for circularity, due to advances  
225 in waste management, ecodesign and re-X strategies.

- 226 • A circular economy is implemented, prioritising waste reduction, resource efficiency, and  
227 a shift from the 'take-make-dispose' model.
- 228 • A notable increase in SRM recycling and recovery rates, indicating an efficient use of  
229 resources.
- 230 • A larger emphasis on designing products for reuse and recycling, making waste a valuable  
231 resource rather than a problem.
- 232 • More extensive use of renewable energy and clean technologies in SRM production and  
233 use, supporting a low-carbon economy.
- 234 • Collaboration between stakeholders — including industry, government, and consumers —  
235 improves, enhancing the implementation of circular practices.
- 236 • New business models like leasing and take-back schemes emerge, altering traditional  
237 consumption patterns [geissdorfer2020circbusinessmodels].
- 238 • Digitalisation and data use are heightened to improve efficiency and traceability, aiding  
239 in effective resource management.
- 240 • Investment in research and development for circular economy technologies increases,  
241 driving innovation and adoption.
- 242 • Awareness and education around sustainable consumption and production practices are  
243 amplified, leading to behavioural changes in society.
- 244 • Reliance on imports decreases, suggesting greater self-sufficiency and sustainability.
- 245 • The creation of new jobs within the recycling, recovery and re-X sectors boosts the  
246 economy and alleviates social inequality.
- 247 • Stricter waste regulations and product design guidelines are introduced, accelerating the  
248 transition towards circularity.

## VII. Acronyms

Table O.1: List of acronyms

| Acronym | Definition  |
|---------|---|
| AI      | Artificial Intelligence   |
| BAU     | Business as Usual   |
| BATT    | Waste Batteries   |
| CDW     | Construction and Demolition Waste                                     |
| CE      | Circular Economy  |
| CRM     | Critical Raw Material   |
| EEE     | Electrical and Electronic Equipment                                   |
| ELV     | End-of-Life Vehicles  |
| EoL     | End-of-Life   |
| EoU     | End-of-Use  |
| EoW     | End-of-Waste  |
| EU      | European Union  |
| EU27+4  | EU + Iceland, Norway, Switzerland and the United Kingdom              |
| EPR     | Extended Producer Responsibility                                      |
| GDP     | Gross Domestic Product  |
| LCA     | Life Cycle Assessment   |
| MIN     | Mining Waste  |
| R&D     | Research and Development  |
| REACH   | Registration, Evaluation, Authorization, and Restriction of Chemicals |
| SLASH   | Slags and Ashes   |
| S-LCA   | Social Life Cycle Assessment  |
| SRM     | Secondary Raw Material  |
| UNFC    | United Nations Framework Classification for Resources                 |
| WEEE    | Waste Electrical and Electronic Equipment                             |
| WFD     | Waste Framework Directive   |

# VIII. Terminology (abbreviated)

The following table provides an abbreviated list of terminology used in this report.  
See section 5.1 for a complete list.

Table O.2: List of terminology (abbreviated)

| Term                   | Definition  |
|------------------------|---|
| Backcasting            | A method for predicting future trends based on a desired future state.  |
| Business-as-usual      | A scenario that assumes no significant changes in current trends and policies.  |
| Circular economy       | An economic system that prioritises waste reduction and resource efficiency.  |
| Critical Raw Material  | A raw material that is economically and strategically important to the EU, but with a high risk of supply disruption. |
| Forecasting            | A method for predicting future trends based on historical data.   |
| Recovery               | The process of recovering SRMs from waste streams.  |
| Re-X                   | A general term for circular strategies such as reuse, repair, refurbishment, remanufacturing and recycling.           |
| Scenario               | A plausible and coherent description of how the future may develop based on a set of assumptions.                     |
| Secondary Raw Material | A material that has been recovered from waste and can be used as a substitute for a primary raw material.             |
| Storyline              | A qualitative description of a scenario, including the key drivers, actors and events.                                |

# IX. Description of FutuRaM work package task 2.1

## Associated milestones

Table O.3: Milestone list

| Milestone | Milestone name   | WP | Due date  | Resp. partner | Means of verification  |
|-----------|--|----|-----------|---------------|--|
| MS11      | Mapping of published scenarios and Story-line/scenario description | 2  | Dec. 2023 | ULEI          | Datasets on available scenarios are fed into D1.1 and qualitative descriptions of 3 futures for the six waste streams are circulated |

## Associated subtasks

Table O.4: Subtask list

| WP | Task | Sub Task | Name                             | Waste Group   | Description of sub-task   | Start | End | Contributors  | Status  |
|----|------|----------|----------------------------------|---------------|---|-------|-----|---|---------|
| 2  | 2.1  | 2.1      | Scenario mapping                 | Cross-Cutting | Map various studies from the academic, policy, and grey literature for future scenarios and assess the applicability within FutuRaM   | M01   | M05 | WEEE Forum, UNITAR, BRGM, Chalmers, GTK, LMU, RECHARGE, SGU, TUB, Leiden Uni, VITO, Empa, UCL | x       |
| 2  | 2.1  | 2.2      | Scenario methods                 | Cross-Cutting | Compile various methodologies for scenario development and assess their applicability for developing scenarios on material recovery and circular economy for Europe         | M02   | M05 | WEEE Forum, UNITAR, BRGM, Chalmers, GTK, LMU, RECHARGE, SGU, TUB, Leiden Uni, VITO, Empa, UCL | x       |
| 2  | 2.1  | 2.3      | Scenario storylines              | Cross-Cutting | Flesh out the storylines of the 3 main scenarios  | M05   | M08 | UNITAR, Chalmers, TUB, Leiden Uni   | x       |
| 2  | 2.1  | 2.4      | Qualitative scenario development | Cross-Cutting | Use the chosen methods and qualitative methods to develop the three main scenarios to be used in FutuRaM (e.g. BAU, increased material recovery, and full circular economy) | M07   | M11 | UNITAR, Chalmers, SGU, Leiden Uni, VITO, UCL  | DRAFTED |

257 **Chapter 1**

258 **Methodology**

## 1.1 The conceptual framework for scenario development

The conceptual framework for scenario development is based on the following principles.

The scenarios should:

- Be based on the best available scientific knowledge and data.
- Provide a coherent and consistent picture of the future.
- Provide decision makers with knowledge related to the possible consequences of their decisions.
- Consider a range of plausible future outcomes, accounting for uncertainties and alternative trajectories.
- Be developed in a participatory and collaborative manner, involving relevant stakeholders and experts.
- Be transparent and well-documented, allowing for replication and further analysis (e.g., publication in peer-reviewed journals and open-access repositories)
- Be flexible and adaptable, allowing for updates and adjustments as new information becomes available.
- Consider the interconnections and interactions between different sectors, waste streams, and policy domains.
- Take into account the broader societal, economic, and environmental context in which the waste streams operate.
- Incorporate a long-term perspective, considering the potential impacts and implications over several decades.
- Capture both quantitative and qualitative aspects, integrating data-driven modelling with qualitative narratives and storylines.

- 282 • Be regularly reviewed and updated to reflect evolving knowledge, technological advance-  
283 ments, and policy developments.
- 284 • Be used as a tool for learning and exploration, encouraging dialogue and collaboration  
285 among stakeholders.
- 286 • Inform policy and decision-making processes, providing insights into the potential con-  
287 sequences of different choices and interventions.
- 288 • Be communicated effectively to a wide range of audiences, ensuring accessibility and  
289 clarity of information.
- 290 • Contribute to the advancement of knowledge and understanding in the field of waste  
291 management, resource recovery, and circular economy.

292 By adhering to these principles, the FutuRaM project aims to develop robust, informative,  
293 and policy-relevant scenarios that support sustainable decision-making and contribute to the  
294 transition towards a more circular and resource-efficient economy. The methodology ensures  
295 that the scenarios capture the complexity and interconnectedness of the waste streams, taking  
296 into account, where possible, factors such as legislation, technology, geopolitics, and societal  
297 values. Ultimately, the goal is to provide decision-makers with valuable insights and tools to  
298 navigate the challenges and opportunities associated with secondary raw materials in a rapidly  
299 changing world.

## 300 1.2 Scenario storyline development process

301 Building scenarios involves several steps and methodologies, which can vary depending on the  
302 specific context and objectives [bishop2007scenarios, dreborg1996essence, cordovapozo2023scenarios,  
303 sardesai2021, amer2013, boerjeson2005, skea2021outlooks, vannotten2003scenario]. The  
304 following section provides an overview of the scenario development process used in FutuRaM.  
305 Figure 1.1 provides a visual representation of the process.

### 1.2.1 Step 1: Define the scope and objectives

#### Scope and objectives of the scenario development process

The scope and objectives of the scenario development process are defined in the context of the overall aim, scope, and objectives of the FutuRaM project.

##### **Aim:**

FutuRaM will develop the Secondary Raw Materials knowledge base on the availability and recoverability of secondary raw materials (SRMs) within the European Union (EU), with a special focus on critical raw materials (CRMs). The project research will enable fact-based decision-making for the recovery and use of SRMs within and outside the EU, and disseminate the data generated via an accessible knowledge base developed in the project.

##### **Scope:**

FutuRaM will establish a methodology, reporting structure, and guidance to improve the raw materials knowledge base up to 2050. FutuRaM will focus on six waste streams: batteries; electrical and electronic equipment; vehicles; mining; slags and ashes; and construction and demolition. It will integrate SRM and CRM data to model their current stocks and flows and consider economic, technological, geopolitical, regulatory, social and environmental factors to further develop, demonstrate and align SRM recovery projects with the United Nations Framework Classification for Resources (UNFC) [unfc2023], a tool that enables a better understanding of the viability of raw material projects. This will enable the commercial exploitation of SRMs and CRMs by manufacturers, recyclers, and investors, and the knowledge base developed in the project will support policymakers and governmental authorities.

Selected objectives of the FutuRaM project are presented in Table 1.1.

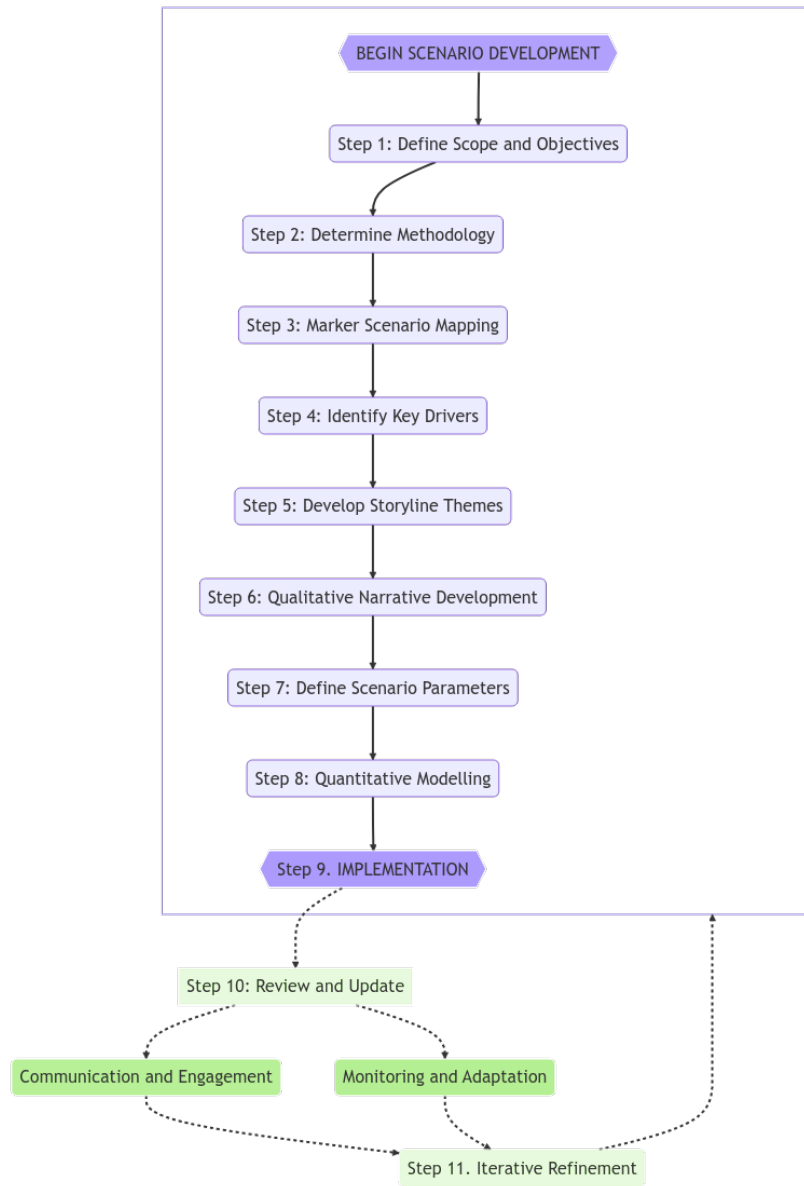

Figure 1.1: Scenario storyline development process

Table 1.1: Selected objectives of FutuRaM

| Need   | Action   |
|--|--|
| A successful transition to a climate-neutral, circular and digitised EU economy relies heavily on a secure supply of raw materials. In order to strengthen EU autonomy and reduce over-dependency, we must boost domestic sourcing, both for primary and SRMs  | FutuRaM will quantify the future availability of SRMs for three future scenarios for the EU material economy, from following current consumption trends to moderate or rapid transitioning toward a climate-neutral, circular, and digitised EU economy (WP2). The material demand and the SRMs supply for each scenario and raw material imports to evaluate EU material autonomy.  |
| Presently, several socioeconomic scenarios have been developed at national, EU, and/or global scales to assess the energy and mobility transition. While some of these studies have partially included CRM demand and focused on the potential supply risks for achieving climate targets, these prospective scenarios have not been effectively harmonised across industrial sectors, and generally lack information on SRMs and the recovery industry in general. Transitions toward sustainable societies are likely to involve major changes and increased complexity in the material economy. Further research into current and future SRMs and CRMs present in the urban mine is thus urgent to prepare the industry for their eventual recovery. In addition, scenarios that include other Circular goals such as lifetime extension need to be better assessed in terms of material cycles | FutuRaM will develop stock-flow models for six waste streams based on holistic scenarios to map current and future material use in the economy of the EU-27 plus Iceland, Norway, Switzerland and United Kingdom (EU27+4) and quantify their eventual end-of-life fate. FutuRaM will extend existing model approaches by a set of distinct scenarios which cover circular economy (e.g., lifetime extension through repair and remanufacturing), high SRMs recoverability, and business as usual. These scenarios will incorporate emerging recycling technologies in line with stakeholder dialogues that consider normative boundary conditions such as carbon neutrality by 2050. |

**Scope definition:**

Given this context, the scope of the scenario development process is to develop a set of plausible scenarios that explore the future of waste management, resource recovery, and circular economy in the EU. The scenarios will be used to identify key drivers and uncertainties that will influence the future of waste management and resource recovery. The scenarios will also be used to evaluate the potential impacts of different policy interventions and technological advancements.

*Thematic scope*

The scenarios will be centred on the six waste streams of FutuRaM: WEEE, ELV, BAT, CDW, MIN, and SLASH. Additionally, consideration will be given to sectors and policy domains that are relevant to these waste streams and the general context of the system. These include manufacturing, energy, and transportation, as well as policies related to the environment, the economy, society, technology, and geopolitics.

*Geographic scope*

The scenarios will be developed for the EU-27 plus Iceland, Norway, Switzerland and the United Kingdom (EU27+4). The scenarios will consider the current and future waste management practices and resource recovery technologies in these countries. Additionally, the scenarios will consider the current and future policies and targets related to waste management and resource efficiency in these countries. To some extent, the scenarios will also consider the current and future trade relationships between these countries and other countries around the world.

*Temporal scope*

The scenarios will be developed for the time horizon of 2025–2050. This time horizon is aligned with the long-term targets of the EU, including the EU Green Deal, the EU Circular Economy Action Plan, and the EU Industrial Strategy. The discrete stages in the forecasts are planned to be: 2025, 2030, 2035, 2040, 2045 and 2050. The temporal resolution of the scenarios will be determined during the quantification phase of the scenario development process. While it is possible to develop scenarios with a high (or even continuous) temporal

356 resolution, that of these scenarios will be determined based on the availability and quality of  
357 data. It is important to acknowledge that providing too high a temporal resolution may lead  
358 to a false sense of accuracy and precision. Furthermore, the scenarios will be developed with  
359 the understanding that the further into the future we look, the more uncertain the predictions  
360 become [amer2013].

#### 361 **Aims and objectives definition**

362 The specific objectives of the FutuRaM scenario-building process are presented in Table 1.2.

Table 1.2: FutuRaM WP2 aims and objectives

| Aim   | Objective   |
|---|---|
| Quantifying the current and future availability of secondary raw materials (SRM), particularly critical raw materials (CRM), for the identified waste streams from 2025 until 2050        | Developing a set of plausible scenarios that encompass these waste streams and provide quantitative estimates of the current and future availability of SRM and CRMs.   |
| Informing private and public sector decision-making processes by assessing the impacts of different legislative and policy strategies related to waste management and resource efficiency | The scenarios will cover a range of such strategies, grouped in coherent sets in each of the three storylines including recycling, reuse, remanufacturing, and landfilling. Integration of the scenario with the system model will allow assessment of the impacts of these strategies on not only the availability of SRM and CRMs, but also on the environment, the economy, and society. |

### Consideration of EU legislation and policy targets

The scenarios developed in FutuRaM include the targets that the EU is setting for specific elements/materials/waste streams, following, in particular, the ambitions of the EU Green Deal [eu2019greendeal] and the proposed critical raw materials (CRM) legislation [eu2023crmact]. Additionally, the consumer-product-centric waste streams BATT, ELV, and WEEE have specific EU legislation that will be considered in the scenarios.

### General policies and legislation

**The EU Green Deal [eu2019greendeal]** is a set of policy initiatives by the European Commission with the overarching aim of making the EU climate-neutral in 2050. This policy portfolio is a response to the Paris Agreement and the United Nations Sustainable Development Goals and it covers a wide range of economic sectors with an emphasis on investments toward building up local, 'sustainable' industries. The scope of FutuRaM is aligned with the EU Green Deal's goal of ensuring the sustainable sourcing and use of raw materials, reducing dependency on imports, and promoting resource security. These goals can conflict with each other, however, and the modelling in FutuRaM will explore the trade-offs between them (e.g., optimising local sourcing may result in higher negative externalities).

**The EU Circular Economy Action Plan [eu2020circ]** is a policy framework developed by the European Commission to promote the circular economy in the European Union. It sets out a comprehensive set of measures and targets to improve resource efficiency, reduce waste, and foster sustainable production and consumption. The Action Plan includes initiatives related to product design, waste management, recycling, and resource efficiency, among others. The Action Plan is a key element of the European Green Deal and it is closely linked to the EU Industrial Strategy.

### The plan:

- Aims to promote the transition to a more circular economy in the EU
- Sets out a range of measures to promote the sustainable use of resources, reduce waste, and increase recycling

- 390 • Includes proposals for new legislation, such as an EU-wide framework for the circular  
391 economy, and revisions to existing legislation, such as the WEEE Directive
- 392 • Emphasizes the importance of product design for the circular economy and proposes  
393 measures to promote eco-design and repairability
- 394 • Includes initiatives to promote the use of secondary raw materials, such as the establish-  
395 ment of a European Raw Materials Alliance
- 396 • Aims to reduce greenhouse gas emissions and improve resource efficiency in the EU
- 397 • Calls for increased cooperation and dialogue among stakeholders in the circular economy.

398 **The Critical Raw Materials Act (CRM act) [eu2023crmact]** is a proposed EU regulation that  
399 aims to ensure a secure and sustainable supply of raw materials to the EU. The Act identifies a  
400 list of strategic raw materials, which are crucial to technologies important to Europe's green and  
401 digital ambitions and for defence and space applications, that are subject to potential supply  
402 risks. The regulation will cover the entire raw materials value chain, from primary extraction to  
403 manufacture to its potential recovery as a secondary raw material.

404 By 2030, one single 'third country' (ex-EU, ex-Schengen) country shall produce not more  
405 than 65% of the EU's annual consumption of each strategic raw material. Clear benchmarks  
406 have been set for the domestic capacities of the EU in 2030:

- 407 • Extract at least 10% of the EU's annual consumption
- 408 • Process at least 40% of the EU's annual consumption
- 409 • Recycle at least 15% of the EU's annual consumption

410 These benchmarks have been included in the scenarios developed in FutuRaM. Specifically,  
411 in the Recovery scenario, where the emphasis is on the recovery of materials from waste  
412 streams and the Circularity scenario where the emphasis is on the implementation of 're-X'  
413 strategies, such as recycling, remanufacturing, and reuse. These benchmarks are considered  
414 too optimistic to be included in the Business-as-usual scenario as they suggest near-complete  
415 recovery for several elements.

## 416 Waste stream-specific legislation and policy targets

417 With respect to the waste streams that are analysed in FutuRaM, the following waste stream-  
418 specific developments aligned with EU targets have been considered:

- 419 • BATT: Battery and waste battery regulation (2023) [eu2023batt]
  - 420 – Establishes rules for the collection, treatment, and recycling of batteries and accu-  
421 mulators in the EU
  - 422 – Requires Member States to set up collection and recycling systems for waste bat-  
423 teries and accumulators
  - 424 – Sets specific recycling targets for different types of batteries and accumulators
  - 425 – Prohibits the use of certain hazardous substances in the manufacturing of batteries  
426 and accumulators
  - 427 – Requires labelling and information for consumers on the proper disposal of batteries  
428 and accumulators
  - 429 – Requires producers to take responsibility for the costs of collecting, treating, and  
430 recycling waste batteries and accumulators
  - 431 – Aims to reduce the environmental impact of batteries and accumulators throughout  
432 their life cycle.
- 433 • BATT: Introduction of battery passport in 2026 [eu2020batt]
- 434 • Mandatory minimum levels of recycled content for industrial, and vehicle batteries.
- 435 • Batteries incorporated in appliances have to be removable and replaceable by 2027.
- 436 • ELV: Proposed revision currently under review [eu2023elv]:
  - 437 – Sets out rules for the collection, treatment, and recycling of end-of-life vehicles  
438 (ELV) in the EU
  - 439 – Requires Member States to set up collection systems for ELV and ensure that they  
440 are treated and recycled in a more environmentally sound manner.

- 441       – Enforce collection targets, ban export of unroadworthy vehicles.
- 442       – Strengthen ‘Extended Producer Responsibility’ to encourage better quality waste
- 443       treatment.
- 444       – Proposes provisions for the design and dismantling of certain CRM-rich compo-
- 445       nents.
- 446   • WEEE Directive (about to be evaluated with a review likely in 2024):
  - 447       – Sets out rules for the collection, treatment, and recycling of waste electrical and
  - 448       electronic equipment (WEEE) in the EU
  - 449       – Requires Member States to establish collection systems for WEEE and ensure that
  - 450       it is treated and recycled in an environmentally sound manner
  - 451       – Sets collection and recycling targets for different types of WEEE
  - 452       – Requires producers to take responsibility for the costs of treating and recycling
  - 453       WEEE
  - 454       – Requires the use of the waste hierarchy for WEEE management
  - 455       – Aims to prevent the generation of WEEE and promote its reuse and recycling
  - 456       – Requires the labelling of electrical and electronic equipment to facilitate its proper
  - 457       disposal.
- 458   • CDW: Inside the CDW stream are important waste flows such as wind turbines and solar
- 459   panels. The permanent magnets in wind turbines are a source of rare earth elements
- 460   (REEs) and the solar panels contain indium and gallium. The CRM Act will also cover the
- 461   recycling of these waste flows.
- 462   • MIN: The CRM Act will also cover the mining waste stream. As stated by the European
- 463   Commission [eu2023crmqla]:

464       The act promotes the recovery of critical raw materials from mining waste. The

465       EU, due to its history of mining, has numerous old mining sites and tailings

466       across the EU which can contain precious critical raw materials, but whose

467       potential has not been analysed so far. The Act obliges current operators

468       to assess the possibility of such recovery and to gather information on the

critical raw materials content of the waste they are generating as well as on the waste stored on their sites. For closed and abandoned mines, the Act makes Member States responsible for gathering this data – from permitting files as well as targeted sampling campaigns – and publishing it in an openly accessible database. This will allow potential operators to identify potential sites of interest and implement such recovery projects with public authorities.

#### **Extent of policy and legislation inclusion in the scenarios**

The targets that result from the planned and ongoing review processes are non-negotiable and legally binding and thus should be incorporated into our scenarios. These targets, however, are only applicable to post-consumer products, namely WEEE, BAT and ELV. This envisioned future in which legally binding targets for collection, reuse and/or material recycling are achieved can be implemented as the Recovery scenario. If there are no targets set for a specific consumer product category, then approach targets similar to the WEEE directive and in line with the EU Green Deal. For the Recovery, and especially for the Circularity scenario, FutuRaM will also consider the effects of proposed ecodesign requirements for sustainable products (e.g., longer lifetimes, increased reusability, repairability, recyclability).

However, for waste that does not consist of discarded consumer products, but instead results from industrial production activities, in particular for MIN and SLASH, we must still produce specific scenarios related to mining, metallurgy, and waste and fuel combustion. The production of new mining wastes will depend on new local mining activity. Predicted production in the EU until 2050 will be forecast (equally across the three scenarios) and the flows into the MIN waste stream can be calculated with the respective transfer coefficients. The recovery of historical MIN stock, which is a target of the CRM Act, should be modelled differently. It requires a hypothesis about the percentage of historical tailings recoverable by commodity and country.

The scenarios will account for increasing resource use effectiveness and production process efficiency, thus indicating lower volumes and quality of generated production residues (both by-products and waste such as red mud, waste rock, slags, etc.) per unit of product (expressed

497 either as product mass or product value), whether that product is a metal (e.g., a copper cathode),  
498 metal alloy (e.g., aluminium alloy n° 5183) or metal product (e.g., cold rolled stainless steel  
499 sheet).

500 Excepting the BAU storyline, WEEE, ELV, and BATT waste material recovery will follow the  
501 targets in the EU. For SLASH and MIN, we will evaluate recent trends in waste generation and  
502 extract plausible ranges of generation toward 2050. For CDW, embedded WEEE will follow  
503 EU targets, and bulk waste will incorporate storylines and scenarios that are congruent with  
504 predicted demolition rates (where renovation is the alternative emphasised in the CIR storyline)  
505 Various drivers will be assigned to move between these ranges and will be key to the specific,  
506 harmonized storyline for the scenario. Finally, the targets and storylines will be aligned with  
507 assumptions on technology development.

#### 508 **Consideration of geopolitical developments**

509 The storylines also attempt to consider geopolitical considerations and thus supply chain  
510 resiliency for satisfying the product demand in the scenarios. We must omit, however, possible  
511 changes in waste flow volumes and composition that could arise from any material supply  
512 constraints. The reasoning for this is that it would needlessly confusate the interpretation  
513 of the modelling results as the incertitude of these potentialities is very high and this realm  
514 is outside the scope of FutuRaM's mandate and expertise. The most volatile aspect of the  
515 'criticality calculation' is the risk profile of the producing country. For many material-exporting  
516 nations, this is not something that can be reliably forecast, especially not over the next 30  
517 years. Thus, it will be assumed that the growth in material demand for (among other needs) the  
518 energy and mobility transitions can be satisfied either by an increase in mining and metallurgy  
519 activities within the EU or by growing imports from raw material-producing countries outside  
520 the EU. That is, if we go for increased domestic EU production to minimize geopolitical supply  
521 risk, it may indicate more EU production residue generation even under increased production  
522 efficiency and resource effectiveness. The increase of domestic industrial activity, as a response  
523 to an envisioned increased internal demand, supposes an equivalent rise of societal approval  
524 for mining and refining activities on EU territory. If the increased demand is, however, satisfied

by imports from non-EU countries, which we know have domestic resource consumption also growing significantly due to the energy and mobility transition, our assumption would be to shift the mining and refining activities from EU countries towards resource-rich non-EU countries. This shift would also imply an increased risk for geopolitical instability and/or security of supply of critical raw materials to the EU. This situation is front-of-mind for many in policy and business and the EU is 'applying a policy mix that aims to increase domestic capacity, diversify suppliers, and support the multilateral rules-based trade environment.' However, '...most experts predict that reshoring or nearshoring will be of limited importance. With time, though, resilience may improve through international cooperation, diversification and the accelerated uptake of digital technologies.' [szczepanski2021resilience]

**'Note: supply constrictions will be considered in the model's sensitivity analysis and the codebase will be designed to allow for the optimisation of the SRM recovery system based on any supply-demand value statements.'**

## 1.2.2 Step 2: Determine methodology

### Methodology types and selection criteria

The second step in the scenario development process is to determine the methodology to be used. This involves identifying the most appropriate methods and tools for the specific context and objectives of the scenario development process. The methodology should be selected based on the following criteria:

- **Relevance:** The methodology should be relevant to the specific context and objectives of the scenario development process.
- **Applicability:** The methodology should be applicable to the specific context and objectives of the scenario development process.
- **Feasibility:** The methodology should be feasible given the available resources (e.g., time, budget, expertise, data, etc.).

- 550 • **Transparency:** The methodology should be transparent and well-documented, allowing  
551 for replication and further analysis.
- 552 • **Flexibility:** The methodology should be flexible and adaptable, allowing for updates and  
553 adjustments as new information becomes available.
- 554 • **Accessibility:** The methodology should be accessible to a wide range of stakeholders,  
555 ensuring that it can be understood and used by non-experts.
- 556 • **Effectiveness:** The methodology should be effective in achieving the objectives of the  
557 scenario development process.
- 558 • **Efficiency:** The methodology should be efficient in terms of time, cost, and resources  
559 required to implement it.
- 560 • **Acceptability:** The methodology should be acceptable to stakeholders, ensuring that it is  
561 perceived as fair and legitimate.

562 Further details are given in this section, and the table in ?? provides an overview of the  
563 methods and tools considered, along with a brief description of each and its relevance to the  
564 specific context and objectives of the FutuRaM scenario development process.

### 565 Choice of methodology

566 The grant proposal for the FutuRaM project outlined that there should be at least three scenarios  
567 developed, namely business as usual, recovery, and circularity. This remains the case; however,  
568 during the scenario development process, additional scenarios or scenario dimensions were  
569 considered, including supply chain security and the energy transition.

570 **Considered dimension — Supply chain security:** Due to various political developments in  
571 2022, the question of the security of the EU's supply chains for CRMs was brought into focus.  
572 This led to the proposal from stakeholders to consider a scenario dimension that would explore  
573 the security of the EU's supply chains for CRMs.

574       **Considered dimension — Energy transition:** The energy transition is a key topic in the  
575 EU's policy agenda, and the FutuRaM project is concerned with the role of CRMs in the energy  
576 transition. Therefore, the proposal was made to consider a scenario dimension that would  
577 explore the energy transition in the EU.

578       **Method — Multi-criteria analysis and cross-impact analysis** In order to assess the potential  
579 inclusion of these additional scenario dimensions, a multi-criteria analysis and a cross-impact  
580 analysis were conducted [steubing2016matrix]. The addition of extra dimensions increases  
581 the possible number of scenarios significantly. By assessing the consistency and plausibility  
582 of these combinations with a matrix-based method, it was possible to reduce the number of  
583 scenarios. For example, low progress in the energy transition is unlikely to concur with high  
584 progress in recycling/circularity indicators and can be excluded. In contrast, different levels for  
585 the supply chain security dimension would result in an additional scenario, as this dimension  
586 is considered independent of the others. Ultimately, supply chain security was eliminated  
587 as a scenario dimension. This is due to the consortium's inability to speculate on geopolitical  
588 developments and the added incertitude it would introduce to the scenarios. The potential of  
589 supply constraints will, however, be considered in the future sensitivity analysis of the model,  
590 as well as potentially through an array of explorative multi-object optimisation procedures.  
591 This can produce projects to answer the question, 'What would happen to the SRM system if  
592 element x is constrained, and what would be the optimal response to this constraint?'

593       **Method — Delphi** The Delphi method [hsu2019delphi] was used in the initial stages of  
594 the scenario-building process to gather and aggregate the opinions of experts or stakeholders.  
595 Internal consultation with consortium members who were experts in their respective waste  
596 streams or other aspects of the recovery system was conducted. The method involves steps  
597 such as the selection of experts, generation of initial questionnaires, iterative rounds of re-  
598 sponses, and convergence and consensus building. For the later stages of the process, further  
599 rounds of consultation will be conducted with external stakeholders, including representatives  
600 from industry, academia, and government.

## Choice of Scenario Type

The general types of scenarios are summarized in Table 1.3.

In the context of futures studies, various approaches and methodologies are employed to understand the potential trajectories of future developments [bishop2007scenarios, cordovapozo2023scenarios, skea2021outlooks, amer2013, boerjeson2005]. We can classify scenario studies into three primary categories, each addressing distinct questions about the future. These categories are tailored to better align with the specific objectives of scenario usage:

### Predictive Scenarios (Answering ‘What Will Happen?’):

- **Pros:** These scenarios offer insights into potential future outcomes, aiding in long-term planning.
- **Cons:** They are contingent on assumptions and may not account for unexpected events.
- **Applicability:** Predictive scenarios are valuable when the aim is to forecast future developments under certain conditions.

### Explorative Scenarios (Answering ‘What Can Happen?’):

- **Pros:** Explorative scenarios explore a wide range of potential future scenarios, fostering preparedness for various outcomes.
- **Cons:** They do not prioritize the likelihood or desirability of scenarios.
- **Applicability:** These scenarios are beneficial when considering multiple potential futures and the need to adapt to diverse outcomes.

### Normative Scenarios (Answering ‘How Can a Specific Target Be Reached?’):

- **Pros:** Normative scenarios focus on achieving predefined objectives and offer guidance on strategies to attain them.
- **Cons:** They are inherently normative, starting with specific goals in mind.

- **Applicability:** Normative scenarios are suitable when the objective is to work towards predefined targets and develop actionable plans to reach them.

The choice of scenario category is influenced not only by the characteristics of the system under study but also by the user's worldview, perceptions, and study objectives. Additionally, the user's perspective plays a crucial role in determining the most suitable approach. For instance, the decision to employ predictive, explorative, or normative scenarios hinges on the user's goals and the nature of the questions they seek to answer.

Furthermore, considerations regarding the predictability of the future and the potential for influencing it can impact the selection of scenario types. For example, some users may argue that uncertainty in certain parameters makes long-term predictions less meaningful, while others may see value in using forecasting and optimisation models to stimulate discussions and inform decision-making processes.

In practice, a combination of qualitative and quantitative techniques can be employed to create scenarios tailored to specific needs. For instance, a blend of techniques may be used to generate forecasts, especially when external factors are uncertain. Likewise, strategic scenarios often begin with external scenario generation and proceed to identify available policy options.

The choice of scenario category is driven by the user's objectives, worldview, and perceptions, making it a crucial factor in the scenario selection process. This user-centric approach ensures that scenarios are not only relevant but also effectively inform decision-making processes. While further refinement is needed based on user feedback, this report provides valuable guidance for scenario use.

Table 1.3: (adapted from [boerjeson2005])

| Scenario category                                | Scenario type | Quantitative/qualitative                         | Time-frame      | System structure         | Focus on internal or external factors    |
|--|---------------|--|-----------------|--------------------------|--|
| Predictive<br><i>what will happen?</i>           | Forecasts     | Typically quantitative, sometimes qualitative    | Often short     | Typically one            | Typically external                       |
|  | What-if       | Typically quantitative, sometimes qualitative    | Often short     | One to several           | External and, possibly, internal         |
| Explorative<br><i>what can happen?</i>           | External      | Typically qualitative, quantitatively possible   | Often long      | Often several            | External                                 |
|  | Strategic     | Qualitative and quantitative                     | Often long      | Often several            | Internal under influence of the external |
| Normative<br><i>how can a target be reached?</i> | Preserving    | Typically quantitative                           | Often long      | One                      | Both external and internal               |
|  | Transforming  | Typically qualitative with quantitative elements | Often very long | Changing, can be several | Not applicable                           |

645 The scenarios developed in the FutuRaM project are a combination of predictive and  
646 normative:

647 • **BAU:**

648 *What will happen if current trends continue?*

649 This scenario is predictive in nature, based on the assumption that the current trends and  
650 developments in waste management and resource recovery systems will continue into  
651 the future.

652 • **Recovery:**

653 *What will it take to achieve the EU's targets for material use and recovery?*

654 *Focus on technology*

655 This scenario is normative, focusing on manipulating the technology and infrastructure  
656 of the recovery system to achieve the EU's targets and mandates.

657 • **Circularity:**

658 *What will it take to achieve the EU's targets for material use and recovery?*

659 *Focus on re-X strategies*

660 This scenario is a combination of normative and explorative, considering the targets and  
661 mandates of the EU's circular economy action plan and exploring re-X strategies in the  
662 recovery system.

663 The methodology and scenario types were selected based on their relevance, applicability,  
664 feasibility, transparency, flexibility, accessibility, effectiveness, efficiency, and acceptability to  
665 the scenario development process.

### 666 1.2.3 Step 3: Marker-scenario mapping

#### 667 Justification and methodology

668 This preliminary step in the scenario development process involves conducting a literature  
669 study to identify existing scenarios that are relevant to the FutuRaM project. This step is crucial

as it serves several important purposes and provides valuable insights for the overall scenario development process. It helps the scenario development team to build on existing knowledge, identify relevant scenarios, gain insights and inspiration, fill knowledge gaps, and enhance credibility and comparability.

**Building on existing knowledge:**

Conducting a literature study allows the FutuRaM project team to tap into existing knowledge and expertise in the fields of waste management, resource recovery, and circular economy. It provides a foundation of existing scenarios that have been developed by other researchers, organizations, or institutions. By building on this existing knowledge, the FutuRaM project can leverage the insights, methodologies, and findings from previous scenario studies, saving time and resources.

**Identifying relevant scenarios:**

Marker scenario mapping helps identify scenarios that are relevant to the specific objectives and scope of the FutuRaM project. By reviewing the literature, the project team can assess the applicability of existing scenarios to their research questions and determine which scenarios align with the waste streams, sectors, and policy domains being considered. This step ensures that the scenarios selected for further analysis are well-suited to address the project's goals.

**Gaining insights and inspiration:**

Reviewing existing scenarios provides the FutuRaM project team with valuable insights and inspiration for the development of their own scenarios. It allows them to understand the different approaches, assumptions, and methodologies used in previous scenario studies. This knowledge can inform the design and structure of the FutuRaM scenarios, helping to ensure a rigorous and well-founded approach.

**Filling knowledge gaps:**

Marker scenario mapping helps identify any gaps or areas of limited knowledge in the existing scenario landscape. It allows the FutuRaM project team to identify topics or aspects that have not been adequately addressed in previous scenarios. This awareness of knowledge gaps can guide the project team in focusing their efforts on areas where new insights and contributions can be made, leading to a more comprehensive and innovative scenario development process.

**Enhancing credibility and comparability:**

By conducting a literature study and referencing existing scenarios, the FutuRaM project can enhance the credibility and comparability of their own scenarios. The project team can reference and compare their findings, assumptions, and results with those from previous studies, contributing to the overall body of knowledge in the field. This promotes transparency, robustness, and consistency in the scenario development process and allows for better benchmarking and evaluation of the FutuRaM scenarios.

**Content of the marker scenario mapping for application to FutuRaM's scenarios**

section 5.3 presents an overview of the marker scenarios considered in the FutuRaM project. The table is not intended to be exhaustive but rather to provide an overview of the different scenarios that have been developed in the fields of waste management, resource recovery, and circular economy.

**1.2.4 Step 4: Identification of key drivers of change**

In this step, the key drivers of change that will shape the future of the scenarios are identified. Key drivers are the factors or forces that have a significant influence on the waste management system and its development over time. These drivers can be social, economic, technological, environmental, or policy-related.

The purpose of identifying key drivers of change is to understand the factors that will have the greatest impact on waste management and to ensure that the scenarios capture the range of possible outcomes influenced by these drivers.

The process of identifying key drivers involves a combination of literature review, expert consultations, and stakeholder engagement. It requires a comprehensive analysis of relevant trends, uncertainties, and emerging issues that may affect the waste management system.

The key drivers identified in this step will be used to develop the storyline themes and scenario parameters in the next step.

Figure 1.2 illustrates the process of identifying key drivers of change.

### Methodology and results of this stage in FutuRaMs scenario development:

The overall goal of this process is to identify and include elements in the storylines and scenarios that are relevant, plausible, and influential in shaping the future. The selection, screening, and categorization steps ensure that the elements chosen for the development of storylines and scenarios are consistent, coherent, and aligned with the objectives and scope of the scenario exercise.

#### 1. Preliminary collection:

This step involved gathering a pool of potential elements that could be included in the storylines and scenarios. These elements were derived from expert input from waste streams and the scenario development team including taking knowledge from the literature review and existing scenarios identified in Step 2 — Marker scenario mapping.

This step was conducted using the PESTLE analysis framework. The PESTEL (or PESTLE) framework is a strategic tool used to understand the macro-environmental factors that can affect a system. A PESTEL analysis can help identify opportunities and threats linked to each of these factors, understand the broader context and shape scenarios accordingly [kokkinos2023methodspestel, sansa2021methodspestel].

The acronym PESTEL stands for:

- **Political:** These factors refer to the impact of government policies, regulations, and political stability. This includes issues like tax policy, labour laws, environmental regulations, trade restrictions and reforms, tariffs, and political stability.
- **Economic:** These factors relate to the broader economic environment, including factors like economic growth, exchange rates, inflation rates, interest rates, disposable income of consumers and businesses, and the general health of the economy.
- **Sociocultural:** These factors include societal trends and characteristics that could affect your business. They include demographic trends (like age, gender, and ethnic-

ity), cultural trends, lifestyle preferences, consumer attitudes, and broader societal expectations.

- **Technological:** These factors refer to the impact of emerging technologies, research and development activities, automation, the rate of technological change, and the adoption of technology within your market.
- **Environmental:** These factors refer to ecological aspects that can affect a system. This includes environmental regulations, consumer attitudes towards sustainability, climate change, and other natural events.
- **Legal:** These factors include laws and regulations with which your business must comply. These can include labour law, consumer law, health and safety law, and restrictions on the import or export of goods.

The 68 elements identified in the initial screening stage are listed in section 5.4.

## 2. Screening:

In the screening step, the collected elements are evaluated and assessed based on specific criteria. This was conducted through a literature study and internal consultation of scientists in the project. This evaluation helps determine the relevance, reliability, and significance of each element for the development of storylines and scenarios. Many elements were aggregated, especially if they were deemed to follow similar trends to others (e.g., recyclability mandates and improved recyclability in project design). Elements that did not meet the predefined criteria or were deemed irrelevant, 'un-modellable' or unreliable were excluded from further consideration (e.g., corruption, data protection, and supply chain conflict).

The 28 elements that were identified in this stage are listed in section 5.5.

In Figure 1.3, an excerpt of a spreadsheet illustrates part of the screening process for the FutuRaM scenarios which was informed by the waste streams. In this exercise, the elements were evaluated based on their relevance to the waste streams and their potential impact on the waste management system. The elements were also assessed based on their plausibility and likelihood of occurrence in the future. The elements that

778        were deemed relevant, plausible, and influential were included in the storylines and  
779        scenarios.

Figure 1.2: An illustration of the process used for identifying key drivers of change

| THIS TABLE IS FOR THE ASSESSMENT OF THE RELEVANCE OF EACH SCENARIO ELEMENT TO INDIVIDUAL WASTE STREAM FLOWS | ELV         |                        |         | BAT                |                      |                            |              |         | WEEE                         |                |               |                          |            |                        |

Figure 1.3: An excerpt of a spreadsheet used as part of the screening process

### 780 3. Assessment

781 Once the screening process was complete, the remaining elements were aggregated and  
782 categorised based on their thematic relevance or characteristics. This categorisation helps  
783 organize the elements into meaningful groups or themes that align with the objectives  
784 and scope of the scenarios.

785 The 21 elements that were identified in this stage are listed in Table 1.4. Note that CIR  
786 and REC are very similar for many elements, the main difference being the way in which  
787 the targets are achieved. That is, for CIR, re-X strategies are promoted, whereas, for REC,  
788 the focus is on technological advancements in the recovery system. This distinction will  
789 have a significant impact on how the scenarios are quantitatively modelled and on the  
790 subsequent outcomes.

Table 1.4: List of drivers and factors identified in the screening phase

| Domain  | Driver/factor | Definition   | Internal | BAU | REC | CIR |
|---|---------------|--|----------|-----|-----|-----|
| Recovery technology   | TECH          | Implementation and advancements in waste recovery technologies               | TRUE     | I   | III | III |
| Product technology  | TECH          | Changes in product function or composition                                   | TRUE     | I   | III | III |
| Integration of SRM system across EU                             | TECH          | Integration of a secondary raw material recovery system across EU countries  | TRUE     | I   | III | III |
| Increased drive for environmental protection                    | ENV           | Growing concern and motivation for environmental conservation                | TRUE     | I   | III | III |
| Progress toward renewable energy targets                        | ECO           | Advancements and achievements in renewable energy generation                 | TRUE     | III | III | III |
| Subsidies and taxation to promote circularity                   | ECO           | Financial incentives or taxes to encourage circular economy                  | TRUE     | I   | II  | II  |
| Participation in re-X activities                                | SOC           | Engagement in refuse-reduce-repair-reuse activities                          | TRUE     | I   | I   | I   |
| Stricter environmental regulations                              | POL           | Tightening of environmental laws and regulations                             | TRUE     | II  | III | III |
| Stricter waste management regulations                           | POL           | Strengthening of waste management laws and regulations                       | TRUE     | II  | III | III |
| Supply chain due diligence laws: implementation and enforcement | POL           | Obligations for identifying and mitigating negative impacts in supply chains | TRUE     | O   | III | III |

Continued on next page

Table 1.4 — Continued from previous page

| Domain   | Driver/factor | Definition   | Internal | BAU | REC | CIR |
|--|---------------|--|----------|-----|-----|-----|
| Compliance with waste targets                      | POL           | Meeting specific waste management and recycling targets                          | TRUE     | 0   | III | III |
| Resource shortages                                 | ENV           | Limited availability of natural resources  | FALSE    | na  | na  | na  |
| Raw material vs SRM prices                         | ECO           | Price dynamics and competition between raw materials and secondary raw materials | FALSE    | na  | na  | na  |
| Climate change impacts/mitigation                  | ENV           | Effects and actions related to climate change                                    | FALSE    | na  | na  | na  |
| International trade and co-operation (vs. autarky) | ECO           | Collaborative trade agreements and global cooperation                            | FALSE    | na  | na  | na  |
| Energy prices                                      | ECO           | Costs and fluctuations in energy prices  | FALSE    | na  | na  | na  |
| Economic growth                                    | ECO           | Overall economic expansion and development                                       | FALSE    | na  | na  | na  |
| Re-industrialisation of EU                         | ECO           | Shift towards increased industrial activities in the EU                          | FALSE    | na  | na  | na  |
| NIMBY to projects                                  | SOC           | Opposition to local projects and developments                                    | FALSE    | na  | na  | na  |
| Population and Urbanisation                        | SOC           | Growth and urban development of population                                       | FALSE    | na  | na  | na  |
| CO2 market price                                   | ECO           | Price and market dynamics of carbon emissions                                    | FALSE    | na  | na  | na  |
|  |               |  |          |     |     |     |

#### 791 4. Categorisation

792 The scenario elements were then assessed based on their potential impact on the waste  
793 management system. For each element, an assessment was made as to whether it was  
794 within the scope of FutuRaM to include them as variables in the models, and therefore  
795 also the scenarios and their storylines. Those deemed to be within the scope are 'internal'  
796 and will be intensively researched and modelled (e.g., composition and design changes).  
797 Those deemed to be outside the scope are 'external' and will be included in the storylines,  
798 will vary over time, but will not vary across the three scenarios (e.g., population and  
799 GPD). Those deemed to be outside the scope and also outside the influence of the  
800 waste management system are 'outside' and will not be included in the storylines or  
801 scenarios, though, in some cases, may be considered in the sensitivity analysis (e.g.,  
802 supply constraints).

#### 803 Justification for keeping elements outside of the scenario models:

804 The purpose of the FutuRaM project is not to provide all-encompassing scenarios that attempt  
805 to capture every possible future development. Such scenarios are inherently inaccurate and  
806 can give a false sense of certainty to the model's outcomes. Instead, the focus of FutuRaM is  
807 specifically on the Sustainable Resource Management (SRM) system and its implications for  
808 the future. Therefore, the scenarios developed within FutuRaM should selectively incorporate  
809 elements that have a direct impact on the SRM system.

810 Furthermore, the scenarios should prioritize elements that can be considered as 'policy  
811 knobs', meaning variables or factors that can be adjusted or controlled to test different settings.  
812 By including these, the scenarios can explore the effects of different policy decisions or inter-  
813 ventions on the SRM system's outcomes. This targeted approach ensures that the scenarios  
814 generated are relevant to the project's objectives and facilitate meaningful analysis.

815 It is crucial to avoid excessive complexity and convolution in scenario modelling. When  
816 there are too many convoluted elements included, the results of the modelling exercise can  
817 become, at best, difficult to understand and interpret. At worst, the outcomes may become  
818 practically useless due to the overwhelming interactions and uncertainties introduced by the  
819 complex elements. Therefore, careful consideration is necessary to strike a balance between  
820 incorporating essential factors and maintaining the clarity and usefulness of the scenario  
821 modelling results.

## 822 Examples:

### 823 • Resource shortages:

824 Resource shortages can be highly unpredictable and subject to various external factors  
825 such as geopolitical events, natural disasters, or technological advancements. The precise  
826 timing and extent of resource shortages are challenging to forecast accurately, making it  
827 difficult to include them within the model without introducing significant uncertainty.  
828 This is especially true for the long-term time horizon of the FutuRaM scenarios. This factor  
829 will, however, be considered in the sensitivity analysis of the model and additionally, the  
830 codebase will be designed to allow for the optimisation of the SRM recovery system  
831 based on any supply-demand value statements.

### 832 • Raw material vs SRM prices:

833 The dynamics and competition between raw materials and secondary raw materials  
834 can be complex and influenced by various market factors, technological advancements  
835 and policy interventions. As with resource shortages, these dynamics are challenging  
836 to forecast accurately, making it difficult to include them within the model without  
837 introducing significant uncertainty. It will, however, be possible to couple the model  
838 with a market model to explore the effects of different price dynamics on the SRM  
839 system's outcomes. This could be considered in a multi-objective optimisation procedure  
840 performed as an extension to the model.

## 841 Conclusion

842 The methodology used for the FutuRaM scenario development ensured that the selected  
843 elements were relevant, plausible, and influential. The use of the PESTEL analysis framework  
844 and Delphi method during the preliminary collection phase provided a comprehensive overview  
845 of the macro-environmental factors. Furthermore, the screening process and the assessment  
846 by internal experts ensured that the selected elements were coherent, consistent, and aligned  
847 with the objectives and scope of the scenario exercise. The final list of scenario elements is  
848 suited to the goal of the FutuRaM project — to quantify the future availability of SRMs and to

849 evaluate EU material autonomy — and will be used to develop the three FutuRaM scenarios  
850 into a quantitative model.

### 851 **1.2.5 Step 5: Develop storyline themes**

852 Given that the scenario themes and directions were broadly dictated by the FutuRaM project  
853 charter, the rough shapes of the storyline narratives were already defined. That is: the ef-  
854 fects on the availability of SRMs from the development of the SRM recovery system and the  
855 development of re-X strategies.

### 856 **1.2.6 Step 6: Qualitative narrative development**

857 The scenario storylines will be described in detail in the next section. This step involved taking  
858 the themes defined by the charter and the elements identified in the previous steps and  
859 working with the internal waste stream groups to develop qualitative estimates about how  
860 each of these elements (at their different levels) may have an impact on the amounts and  
861 composition of the SRM flows in their purview.

### 862 **1.2.7 Step 7: Definition of scenario parameters**

863 The scenario parameters are the set of quantitative values or functions that will be used to  
864 define the scenario inputs for the model. These parameters will be defined in the next stages  
865 of the project.

### 866 **1.2.8 Step 8: Quantitative modelling**

867 The scenario quantification will be performed in the next stages of the project.

### 1.2.9 Step 9: Implementation

The scenario implementation will be performed in the next stages of the project.

### 1.2.10 Step 10: Review process

The review process is intended to ensure that the elements included in the storylines and scenarios are relevant, plausible, and consistent with the scenario objectives and scope.

The first stage of the review process is to open the scenario development process to the wider FutuRaM consortium. This will be done by sharing the scenario development process and the results of the assessment and categorization step with the consortium and inviting feedback and suggestions. The feedback will be used to refine the elements and their categorization and to identify any elements that may have been missed in the initial assessment.

The second stage will involve opening the scenario development process to external stakeholders and subject matter experts.

The scenario review process will be performed repeatedly over all stages of the project. This document is a living document and will be updated as the project progresses.

## 882 **Chapter 2**

## 883 **Scenario storylines**

## 884 2.1 Scenario 1: Business-as-usual

### 885 2.1.1 Storyline narrative

886 This scenario envisions the future based on the current situation, extending to 2050 with very  
887 little deviation from present consumption patterns and the secondary raw material (SRM)  
888 system [iea2022worldenergyoutlook]. While there may be advances in some areas such as  
889 resource efficiency, recovery technology, and the energy transition, substantial modifications  
890 remain hindered by economic, social, and political constraints. The primary extraction of raw  
891 materials continues to be the primary source to meet the EU's demand.

892 In the Business As Usual (BAU) scenario, we are projecting the trajectory of the present into  
893 the future, extending up to the mid-century mark, 2050, with minimal disruption to existing  
894 consumption habits and the secondary raw material (SRM) system. This scenario unfolds on  
895 the assumption that the current pace and direction of technological, economic, and social  
896 development continue unhindered, and is characterised by a strong persistence of today's  
897 patterns.

898 In this scenario, we see moderate improvements in resource efficiency, advancements in  
899 recovery technology, and a slow transition towards greener energy sources. However, these  
900 developments are only minor tweaks to the existing system, failing to disrupt or fundamentally  
901 alter the established structure. The potential for transformational change remains largely  
902 untapped due to various hurdles. Economic constraints, social resistance to change, political  
903 inertia, and entrenched interests act as barriers to change, stifling efforts towards a more  
904 sustainable SRM system.

905 Primary extraction of raw materials remains the dominant source for raw materials con-  
906 sumed in the EU, continuing the linear 'take-make-dispose' model of resource consumption.  
907 Base metals are well recycled, given their developed markets and economies of scale but  
908 rare/special metals are wasted because recycling technologies and economics do not allow for  
909 their recovery. Recycling and recovery rates remain stubbornly low, resulting in significant CRM  
910 waste. Meanwhile, material demand continues to rise in tandem with GDP growth, further

911 exacerbating the resource pressure.

912 Moreover, the environmental impacts of mining and extraction persist as a significant  
913 concern. These operations continue to degrade ecosystems, leading to loss of biodiversity  
914 and contributing to climate change [ipcc2024climate]. Simultaneously, the EU becomes  
915 increasingly dependent on imports of SRMs, raising concerns about supply chain security and  
916 geopolitical risks [ipcc2024climate].

917 Innovation in SRM recovery technologies is hampered by a lack of investment and regulatory  
918 support. The focus remains predominantly on cost-effective material production and use, with  
919 little regard for environmental implications or long-term sustainability. Material scarcity and  
920 price fluctuations, therefore, may become a considerable risk to the EU industry, limiting stable  
921 penetration of new recovery technology and threatening economic stability.

922 Moreover, the tightening of environmental regulations is restricted, inadequately addressing  
923 emerging challenges or incentivising sustainable practices. The lack of regulatory progress may  
924 further exacerbate environmental damage and biodiversity loss.

925 In essence, the BAU scenario is characterised by a continuation of current trends and  
926 practices, a future where the potential for a sustainable SRM system is unrealised due to the  
927 stranglehold of prevailing economic, social, and political constraints.

928 In the Business-as-usual (linear economy) scenario, the following are key characteristics:

- 929 • A forecasting model is used to predict the future based on the current situation and the  
930 development of existing trends.
- 931 • Many EU targets for recycling and recovery are not met, and the current linear model  
932 largely persists.
- 933 • Material demand keeps pace with GDP growth, perpetuating a trend of increasing con-  
934 sumption. Primary mining and extraction persist as the leading sources of raw materials,  
935 underlining the dependency on traditional extraction methods.
- 936 • Recycling and recovery rates continue to lag, leading to an accumulation of SRM waste  
937 that signals missed opportunities for resource reuse.

- 938 • The environmental repercussions of mining and extraction, such as land degradation and  
939 water pollution, continue to be a pressing concern, reflecting the ecological toll of this  
940 linear model.
- 941 • The EU's dependency on imports of SRMs escalates, heightening the risk of supply  
942 disruptions. While supply disruption can serve to stimulate investment in new SRM  
943 recovery, volatility stifles innovation and advancements in this field.
- 944 • The industrial focus remains on cost-effective material production and use, disregarding  
945 the long-term sustainability aspect.

## 946 2.1.2 Waste stream specific scenario impacts

947 **BATT (Battery waste)** [helander2023battelv, eu2020batt, halleux2021batt, eu2023batt]

948 In the business-as-usual (BAU) scenario, the management of end-of-life batteries remains  
949 largely unchanged. The lack of technological innovation and regulatory incentives leads to a  
950 continued low recovery rate of valuable materials from battery waste.

- 951 • A growing volume of battery waste due to the increased use of electronic transport and  
952 renewable energy storage systems.
- 953 • Lack of technological innovation and regulatory incentives lead to low recovery rates for  
954 certain battery types and certain elements.
- 955 • Collection systems for battery waste remain sporadic and unstandardised.
- 956 • Primary extraction remains the dominant source of battery materials.
- 957 • Share of LIB will increase (EV, LMT, Industrial LIB uptake)
- 958 • LIB Battery Chemistries will change and new LIB technologies will enter the market.  
959 Though, not with a focus on recycling and recovery.
- 960 • Larger portable batteries: shift towards Li-ion batteries
- 961 • Small format batteries in EEE: no significant change in battery chemistry.

- 962 • Use of critical resources continues but is already decreasing (BATT chemistry already  
963 changing towards less CRM content)
- 964 • Large-scale reuse of batteries is minimal
- 965 • Collection rates do not fulfil the EU targets
- 966 • Recycling efficiencies do not fulfil the EU targets
- 967 • Recovery rates do not fulfil the EU targets

968 **ELV (End-of-Life Vehicles) [eu2023elv, lovik2021elv, tazi2023elv, helander2023battelv]**

969 The BAU scenario maintains the current approach to end-of-life vehicles, with minimal  
970 improvements in the recovery and recycling process. The absence of effective technologies  
971 and regulatory incentives results in low recovery rates of valuable materials from ELVs.

- 972 • Legislation banning new ICEVs from 2035
- 973 • Current recovery technologies are unable to significantly improve the extraction of  
974 valuable materials from ELVs.
- 975 • Consumer demand continues to drive high production of new vehicles.
- 976 • ELV collection systems remain at their current efficiency.
- 977 • A significant proportion of vehicle components continue to end up as waste.
- 978 • Gradual and slow improvement of recycling chain technology efficiency
- 979 • No new legislation to improve recovery and support circular strategies in comparison to  
980 2023

981 **WEEE (Waste Electrical and Electronic Equipment) [parajuly2019weee, un2023weee,  
982 forti2020weee, eu2012weee, eu2012weeerecast]**

983 In the BAU scenario, the treatment of WEEE does not significantly change. The lack of  
984 technological progress and effective regulation results in low recovery rates of valuable materials  
985 from WEEE.

- 986 • Limited improvements in the recovery of valuable materials from WEEE.
- 987 • High consumer demand for new electronics continues to drive high WEEE generation.
- 988 • Ineffective collection systems and lack of public interest result in significant amounts of
- 989 WEEE ending up in landfills.
- 990 • No significant growth in collaboration between government and industry for WEEE
- 991 recovery.
- 992 • The majority of WEEE continues to be treated with common domestic waste, with low
- 993 recycling rates.
- 994 • No groundbreaking technologies and practices to improve recovery and circularity.
- 995 • Reuse of products and components is not widely utilised
- 996 • Changes in legislation (e.g., circular economy and product design targets, targets for
- 997 collection and recycling) are not strictly implemented.
- 998 • The BAU and the Recovery scenarios are similar from the put-on-market perspective
- 999 (e.g., production and consumption remain the same), but it's the recovery stage that
- 1000 makes the difference.

#### 1001 **Mining waste (MIN)**

1002 The BAU scenario sees the continuation of current practices in mining waste management.

1003 The absence of advanced recovery technologies and regulatory incentives leads to low recovery

1004 rates of valuable materials from mining waste.

- 1005 • Limited technological advancements lead to static recovery rates of valuable materials
- 1006 from mining waste.
- 1007 • Continued reliance on primary extraction as the dominant source of raw materials.
- 1008 • Minimal advances in collaboration between government and industry for mining waste
- 1009 recovery.

- 1010 • Low levels of traceability and management of mining waste.
- 1011 • Mining waste remains a significant environmental challenge.
- 1012 • Mining waste recovery projects remain too expensive.
- 1013 • Little incentive for the private sector and public sector, except for monitoring environ-
- 1014 mental risks of existing deposits.

#### 1015 **CDW (Construction and Demolition Waste) [eu2008wastedirective]**

1016 In the BAU scenario, the management of Construction and Demolition Waste (CDW)  
 1017 remains largely unchanged. Lack of progress in recovery technologies and regulatory incentives  
 1018 will lead to low recovery rates of CRM-containing materials from CDW.

- 1019 • Base metals are recovered as they have been [moschen2023cdw], though there are
- 1020 limited improvements and no particular focus on the recovery of CRMs from CDW.
- 1021 • Continued generation of CDW due to the demand in the construction sector.
- 1022 • Renovation as an alternative to new construction is not widely adopted.
- 1023 • The majority of CDW (excluding base metals) continues to be treated as waste or backfill,
- 1024 with low recycling rates.
- 1025 • CDW recovery (including preparation for re-use, recycling and other material recovery,
- 1026 including backfilling)
- 1027 • Recovery of metals remains on already high levels (>90%)
- 1028 • Recovery of minerals remains on already high levels (>70%) by using them as aggregates
- 1029 in road construction and backfilling
- 1030 • Recycling of wind turbines stays around 85% (mainly metals), permanent magnets
- 1031 continue to be recycled as part of the metal fractions

#### 1032 **SLASH (Slags and Ashes)**

1033 In the BAU scenario, SLASH continues to be treated generally as low or negative-value  
 1034 waste. The absence of economically profitable recovery technologies or regulatory mandates  
 1035 leads to low improvements in the recovery rates of CRMs from SLASH.

- 1036 • Increased generation of SLASH because SRMs are not recovered and end up in incinera-  
 1037 tion and smelter residues.
- 1038 • Low quality of SLASH due to:
  - 1039 – poor sorting and separation of waste streams (e.g., consumer electronics and bat-  
 1040 teries, end up in general waste streams and are incinerated)
  - 1041 – high 'contamination' from the above-described failures of segregation.
  - 1042 – large proportion coming from mixed waste incineration
- 1043 • Lack of technological advancements results in low recovery rates of valuable materials  
 1044 from SLASH.
- 1045 • Continued high generation of SLASH due to the reliance on traditional energy sources.
- 1046 • Minimal incentives for the recovery and reuse of materials from SLASH.
- 1047 • Low levels of traceability and management of SLASH.
- 1048 • SLASH continues to be a significant environmental challenge due to the high volume  
 1049 generated.
- 1050 • Some products from SLASH are recovered in low added value, for example, as aggregates  
 1051 for roads or additives in cement.

## 1052 2.2 Scenario 2: Recovery

### 1053 2.2.1 Storyline narrative

1054 In the recovery scenario, the central emphasis is on harnessing sophisticated technologies to  
 1055 salvage SRMs from waste streams at the end of their lifecycle. While there are noticeable strides

1056 towards the incorporation of 'circular design' principles and re-X strategies, they are mostly  
1057 seen at the end-of-life and material demand is akin to that observed in the BAU scenario. This  
1058 is, however, mitigated by the implementation of a comprehensive material recovery system.

1059 In this scenario, the central actor is the waste treatment sector, with the spotlight falling on  
1060 the enhancement of recovery technology. The implementation and optimisation of cutting-  
1061 edge technologies, such as Artificial Intelligence (AI), automation, and advanced robotics, play  
1062 a significant role in revolutionising waste treatment processes. These technologies streamline  
1063 waste sorting, improve the quality of recovered materials, and increase the overall efficiency of  
1064 the recovery process.

1065 This scenario calls for an emphasis on policy development and standardisation to foster  
1066 EU-wide development, integration, and compliance. Here, the role of governments and policy-  
1067 makers becomes crucial in setting more ambitious recovery targets, developing conducive  
1068 regulatory frameworks, and enforcing compliance. This multi-pronged approach also involves  
1069 strengthening cross-border cooperation, harmonising waste management standards, and  
1070 promoting knowledge and technology transfer among EU member states.

1071 To realise more ambitious environmental impact reduction targets, significant progress  
1072 needs to be made in both technological and policy aspects. Enhancing technological capabilities  
1073 will improve recovery rates, while robust policy measures will ensure these advancements are  
1074 integrated into the wider economy in a regulated manner. The future of this scenario depends  
1075 on the successful fusion of advanced technology, regulatory harmonisation, and a commitment  
1076 to continuous improvement in waste management and SRM recovery.

1077 Key characteristics of this technology-promoted recovery scenario include:

- 1078 • This scenario uses a combination of forecasting and backcasting methods to envision  
1079 the future.
- 1080 • The backcasting method is used for scenario factors that are covered by governmental  
1081 targets, starting with the desired outcome and working backwards to the present.
- 1082 • The forecasting method is used for scenario factors that are not covered by governmental  
1083 targets, starting with the current situation and extending to the future.

- 1084 • EU targets for recycling and recovery are met, due to the EU's waste management system  
1085 becoming more expansive, efficient and effective.
- 1086 • Technological innovation drives increased recovery rates of SRMs, enabling the more  
1087 efficient use of waste.
- 1088 • Digitalisation and automation are more extensively used in recycling processes, leading  
1089 to enhanced productivity and accuracy.
- 1090 • There is greater exploration and exploitation of alternative sources such as urban mining,  
1091 waste streams, and tailings, presenting novel opportunities for resource acquisition.
- 1092 • New waste regulations and guidelines for SRM recovery are implemented, enforcing  
1093 better management and extraction of SRMs.
- 1094 • Investment in research and development for SRM recovery technologies experiences an  
1095 upswing, promoting continuous innovation in this field.
- 1096 • Closer collaboration and information sharing between industry and government institu-  
1097 tions streamline processes and expedite decision-making.
- 1098 • New jobs are created in the recycling and recovery sector, offering economic benefits  
1099 and improving overall employment rates.
- 1100 • SRM production and use become more efficient and cost-effective, fostering economic  
1101 sustainability.
- 1102 • Environmental impact from mining and extraction is reduced, signalling a more sustain-  
1103 able approach to resource acquisition.
- 1104 • The EU's dependence on primary extraction is reduced, with SRM recovery becoming a  
1105 more significant source of raw materials.

## 1106 2.2.2 Waste stream specific scenario impacts

1107 **BATT (Battery waste)** [helander2023battelv, eu2020batt, halleux2021batt, eu2023batt]

Under the recovery scenario, end-of-life batteries become a crucial source of secondary raw materials, primarily due to the increased adoption of electric vehicles and renewable energy storage systems. Technological innovation drives the recovery and recycling process, ensuring valuable materials are extracted from waste batteries for reuse.

- Increase in end-of-life batteries due to the growth of electric vehicles and renewable energy storage.
- Advanced recovery technologies facilitate the efficient extraction of valuable materials from battery waste.
- Standardised collection systems enhance the quantity and quality of battery waste available for recovery.
- Industry and government collaboration lead to investments in research and development of battery recovery technologies.
- Battery passports have a strong impact on collection, material recovery rates and recycling rates.
- Collection
  - Portable battery collection increases according to the trend seen in the WEEE waste stream.
  - Improved collection of light means of transport (LMT) batteries.
  - Improved regulation and collection of Industrial batteries.
- Material recovery
  - Improved recycling technologies
  - Battery Pass will improve material recovery
  - Higher recovery rate for lithium
  - Increase in recycling by average weight
  - Recycling of plastics
- Ambitious goals of recycling/recovery rates compete with reuse, so reuse remains low.

- 1134 • Improved public awareness means that fewer batteries end up in the municipal waste  
1135 stream and there is less hoarding.
- 1136 • Against this: there is competition for the batteries from the reuse vs. recycling market.
- 1137 • Design for recycling (DFR):
  - 1138 – Material and composition selection for recycling [helander2023battelv].
  - 1139 – Higher requirements on disassemblability.
  - 1140 – Information available to promote efficient recovery.

#### 1141 **ELV (End-of-Life Vehicles) [eu2023elv, lovik2021elv, tazi2023elv, helander2023battelv]**

1142 The recovery scenario envisions a more effective and technology-driven end-of-life vehicle  
1143 treatment process. Advancements in recovery technologies allow for improved extraction of  
1144 valuable materials from vehicles at their end of life, although consumerism still drives high  
1145 demand for new vehicles.

- 1146 • Innovations in recovery technologies allow for a higher recovery rate of CRM-containing  
1147 materials from ELVs.
- 1148 • The total number of vehicles produced remains high due to consumer demand.
- 1149 • Improved systems for ELV collection are established, ensuring efficient management of  
1150 ELV waste.
- 1151 • Increased collaboration between the government and industry leads to investments in  
1152 ELV recovery technologies.
- 1153 • Focus on managing end-of-life of vehicles
- 1154 • EU recovery targets are reached (currently implemented/proposed targets, but also  
1155 increased and new targets)
- 1156 • Common/bulk materials (Fe, Non-Fe, plastics etc.) and precious metals (Au, Ag, Pd, Pt)  
1157 reach high mass recycling rates and high element recycling rates. Other CRMs currently  
1158 not recovered reach a moderate level of recovery.

- 1159 • For instance,
- 1160     – More advanced dismantling and processing steps (e.g., components and materials)
- 1161     – More specialised recovery of certain components and materials (e.g., electric motors
- 1162         including permanent magnets and embedded REE) as suggested in the proposal
- 1163         for a revised ELV directive.
- 1164     – More public and private interest in developing recycling chains
- 1165     – Increase in collection rate due to increase in participation from the public and
- 1166         businesses, i.e., target-based incentives with strong regulations and monitoring
- 1167 • Design for recycling (DFR):
- 1168     – Higher requirements on ‘disassemblability’.
- 1169     – Information available to enable recovery.

1170 **WEEE (Waste Electrical and Electronic Equipment) [parajuly2019weee, un2023weee,**  
 1171 **forti2020weee, eu2012weee, eu2012weeerecast]**

1172 Under the recovery scenario, WEEE becomes a significant resource for secondary raw  
 1173 materials. Technological advancements in the sector improve the efficiency of WEEE treatment,  
 1174 although the consumerism-driven demand for new electronics remains high.

- 1175 • Advanced technologies enable higher recovery rates of valuable materials from WEEE
- 1176 • Despite advancements in design for recyclability, WEEE generation remains high due to
- 1177     the consumer demand for new electronics
- 1178 • Standardised and segregated collection systems for WEEE are implemented, improving
- 1179     the supply of materials for recovery
- 1180 • Increased industry-government collaboration leads to further development in WEEE
- 1181     recovery technologies
- 1182 • Consumer behaviour remains a significant hurdle for more efficient WEEE management
- 1183 • Higher recycling rate — make full use of the disposed parts. For instance:

- 1184           – more automation of the dismantling and processing steps (e.g., AI)
- 1185           – recycling technologies improvements (e.g., small components recovery is also
- 1186           happening)
- 1187           – more effective collection infrastructure
- 1188           – financial support provided to recyclers/operators
- 1189           – bans on WEEE exports push for increased domestic recycling [huisman2015weee]
- 1190       • 'Design for recovery' principle — Ecodesign mandates changes in weight and composition
- 1191       of EEE so complexity and the type of materials used
- 1192       • Higher public awareness and participation on WEEE issue and management
- 1193       • Higher compliance from the public, the producers and the businesses
- 1194       • Strong regulations and monitoring are in place with higher collection and recycling targets
- 1195       which are set and implemented and fines are set for those who fail to achieve the targets
- 1196       • Focus is given more to the EoL management of WEEE

#### 1197       **Mining waste (MIN)**

1198       Under the recovery scenario, technological advancements enable the extraction of residual  
1199       valuable materials from mining waste, transforming it into a valuable resource.

- 1200       • Technological advancements facilitate the extraction of valuable materials from mining
- 1201       waste.
- 1202       • Despite progress in recovery technologies, primary extraction remains the dominant
- 1203       source of raw materials due to high consumer demand.
- 1204       • Government and industry collaboration support the development of technologies for
- 1205       the recovery of materials from mining waste.
- 1206       • Increased traceability and management of mining waste through digitalisation.
- 1207       • Mining waste remains a significant environmental challenge.

## 1208 **CDW (Construction and Demolition Waste) [eu2008wastedirective]**

1209 Under the recovery scenario, Construction and Demolition Waste (CDW) becomes an  
 1210 important resource for secondary raw materials, though mostly base metals and aggregates.  
 1211 Despite some progress in eco-design and material efficiency, the construction industry contin-  
 1212 ues to generate significant amounts of waste or 'downcycled' materials.

- 1213 • Advanced recovery technologies allow for higher recovery rates of valuable materials  
 1214 from CDW.
- 1215 • Despite improvements in design and material efficiency, CDW generation remains high  
 1216 due to the construction demand.
- 1217 • Eliminating the disposal of any avoidable CDW, through the implementation and expan-  
 1218 sion of incentives, and regulatory measures.
- 1219 • The focus of this scenario is to significantly reduce the amount of CDW that ends up in  
 1220 treatment plants without any useful applications, e.g., landfilling, incineration, and land  
 1221 spreading.
- 1222 • This scenario is characterized by a high recovery rate, achieved via:
  - 1223 – increased investment and enhanced regulatory system in waste management
  - 1224 – leading to more waste recovery infrastructure
  - 1225 – widespread application of selective demolition and on-site waste sorting
  - 1226 .
- 1227 • Recovery of minerals is intensified with a stronger focus on closed-loop recycling (e.g.,  
 1228 concrete waste is used as aggregates in concrete; recovery of cement is explored).
- 1229 • Recovery of other materials like glass, plastics, and wood is also intensified.
- 1230 • Better separation of waste at source leads to a higher quality of secondary raw materials.
- 1231 • Improved recycling of wind turbine blades is notable, especially regarding plastics; per-  
 1232 manent magnets are recycled at a functional level.

### 1233 SLASH (Slags and Ashes)

1234 In the recovery scenario, SLASH are recognized as a potential resource for secondary raw  
1235 materials. Advances in recovery technologies enable the extraction of valuable metals from  
1236 SLASH, however, the total volume of CRMs recovered from this material remains low, except  
1237 in cases of supply constraint.

- 1238 • Advanced recovery technologies allow for the extraction of valuable metals and minerals  
1239 from SLASH.
- 1240 • Despite improvements in energy production, SLASH generation remains significant due  
1241 to the continued reliance on traditional energy sources.
- 1242 • New regulations incentivize the recovery and reuse of materials from SLASH.
- 1243 • Digital solutions enhance the traceability and management of SLASH.
- 1244 • SLASH remains a significant environmental challenge due to the volume generated.
- 1245 • Transferring down-cycling to recycling or even upcycling.
- 1246 • Recycling technology improvements (e.g., cement additives using biomass ash are under  
1247 investigation)
- 1248 • More functional collection infrastructure.
- 1249 • Financial support provided to recyclers/operators.
- 1250 • Introduction of SRM/CRM recovery targets. For example, recovery of P from biomass  
1251 ash for fertilizer. Recovery of Zn and Pb from Zn and Pb smelter slag.
- 1252 • Higher awareness and participation of relevant sectors on SLASH issues and manage-  
1253 ment.
- 1254 • Strong regulations and monitoring are in place with higher collection and recycling targets.

## 2.3 Scenario 3: Circularity

### 2.3.1 Storyline narrative

In this scenario, we move in the direction of the maximum achievable state of material efficiency as government policy, private innovation and social changes are rapidly driving the transition toward a circular economy. The emphasis here rests heavily on re-X strategies that are implemented in the design phase of products (e.g., repairability and re-manufacturability) and that are actualised by changes in consumer behaviour (e.g reduction, refusal, engagement in the 'sharing economy' and curtailment of the 'throw-away' mindset). Further, being enabled by the widespread adoption of 'circular design' principles and improvements in information transparency (e.g., waste tracking and digital product passports) the system for the treatment of post-consumer waste can divert a significant amount of their inflows (to, for example, re-use and re-manufacture) with the residual fraction being readily segregated into purer, more efficiently recoverable, material streams. This scenario envisions a future where government policies are in synergy with private sector innovation and societal changes, driving a wholesale transition towards a circular economy. Unlike the recovery scenario, where the focus is on the end-of-life recovery of materials, this scenario emphasises minimising waste at all stages, starting from the design phase itself.

The emphasis is on re-X strategies that are integrated right from the product design stage. This includes repairability, where products are designed to be easily fixed rather than replaced; and re-manufacturability, where products or their components are designed to be restored to their original state, extending their lifespan and reducing the need for new resources. This scenario calls for a drastic change in consumer behaviour, where reduction in consumption and waste, refusal of non-sustainable options, and active participation in the 'sharing economy' become the norm rather than the exception.

In the circularity scenario, the widespread adoption of 'circular design' principles becomes a cornerstone of production. In a circular design approach, products are designed and produced in a way that considers their entire lifecycle, including eventual disassembly and reuse. This

means that every component of the product can either be biologically broken down without any harm to the environment or technically reprocessed into new products, creating a closed loop of materials.

Additionally, this scenario envisions an improvement in transparency, with measures such as waste tracking and digital product passports becoming standard. Waste tracking allows for efficient management of waste flows, aiding in effective resource planning, while digital product passports provide information about a product's composition and how it can be properly disassembled, reused, or recycled.

### 2.3.2 Waste stream specific scenario impacts

#### BATT (Battery waste) [helander2023battelv, eu2020batt, halleux2021batt, eu2023batt]

In the circularity scenario, battery waste treatment undergoes a massive transformation. The shift towards electric vehicles and renewable energy storage significantly increases the quantity of end-of-life batteries. However, thanks to new regulations, technological advancements, and business models, the majority of battery components are recycled or reused.

- Massive increase in end-of-life batteries due to the shift to electric vehicles and renewable energy storage.
- New regulations incentivise battery manufacturers to design for recycling.
- Battery recycling technologies improve, enabling higher recovery rates of valuable metals.
- Standardised collection systems for battery waste are established, improving the efficiency of the recycling process.
- Service-based business models like leasing ensure manufacturers retain ownership of the batteries, promoting circularity.
- Greater transparency through digital product passports aids in effective battery waste management.

- 1306 • Battery passport and publicly accessible Information from the new Battery Regulation  
1307 (SoH, SoC, Predicted lifetime/warranty, etc.) given by the economic operator that places  
1308 the battery on the market enables high re-use rates.
- 1309 • Increased repairability/modularity.
- 1310 • Reduced demand from 'sharing economy' and more 'sustainable' transport choices.
- 1311 • New emerging technologies more suited for reuse/repair.
- 1312 • Ambitious targets set by business and public policy.

#### 1313 **ELV (End-of-Life Vehicles) [eu2023elv, lovik2021elv, tazi2023elv, helander2023battelv]**

1314 For End-of-Life Vehicles (ELVs), the circular economy model affects the way vehicles  
1315 are designed, used, and discarded. Emphasising extended vehicle life through repair and  
1316 remanufacturing, this scenario also focuses on the recovery of materials from vehicles at the  
1317 end of their life.

- 1318 • Vehicle design shifts towards repairability, upgradability, and recyclability, increasing the  
1319 lifespan of vehicles.
- 1320 • Standardised systems for ELV collection are established, ensuring efficient waste man-  
1321 agement.
- 1322 • Innovative technologies enable higher recovery rates of metals and other valuable mate-  
1323 rials from ELVs.
- 1324 • Service-based models like vehicle leasing and sharing could reduce the total number of  
1325 vehicles produced.
- 1326 • Digital product passports provide information about vehicle components, aiding in effec-  
1327 tive recycling or reuse.
- 1328 • Focus on managing the use-phase of vehicles.
- 1329 • Circular strategies take place before material recovery so that material recovery is “de-  
1330 layed”.

- 1331 • Information available to enable these strategies.
- 1332 • EU vehicles policy has implications for materials in vehicles, such as 'lightweighting' and
- 1333 downsizing
  - 1334 – Increase in average occupancy and average vehicle-kilometres per trip.
  - 1335 – Decrease in average lifetime (in terms of years): As the utilisation factor increases.
- 1336 • Increase in circular strategies due to an increase in participation from the public and
- 1337 businesses, i.e., target-based incentives with strong regulations and monitoring.

1338 **WEEE (Waste Electrical and Electronic Equipment) [parajuly2019weee, un2023weee,**  
 1339 **forti2020weee, eu2012weee, eu2012weeerecast]**

1340 In the circularity scenario, WEEE becomes a valuable resource instead of a disposal challenge.  
 1341 Thanks to product design changes and the application of advanced recovery technologies, a  
 1342 significant percentage of the materials in WEEE is reclaimed and fed back into the production  
 1343 cycle.

- 1344 • Electronic products are designed for longevity, repairability, upgradability, and recyclabil-  
 1345 ity.
- 1346 • Advanced technologies enable higher recovery rates of precious metals from WEEE.
- 1347 • Collection systems for WEEE are improved, ensuring a steady supply of materials to feed  
 1348 the recovery system.
- 1349 • Digitalisation and data use enhance traceability and efficiency in WEEE management.
- 1350 • Service-based models for electronics promote the use of products as a service rather  
 1351 than ownership, reducing WEEE generation [geissdorfer2020circbusinessmodels].
- 1352 • Increased durability and lifespans.
- 1353 • Increased repairability.
- 1354 • More sharing and product-service systems, correspond to a reduction in the lifetime (for  
 1355 some equipment).

- 1356 • More reuse practices (expanded second-hand market).
- 1357 • Less hoarding.
- 1358 • Higher formal collection and recycling rate.
- 1359 • Focus is given more to the production and use phase rather than the EoL (End-of-Life).
- 1360 • 'Design for circularity' principle: Ecodesign mandates repairability, durability, no obsoles-
- 1361 cence, modularity, and that continual software upgrades are possible [eu2023chargers,
- 1362 eu2023chargerspress].
- 1363 • Electronically compatible chargers and battery packs can be used by different products.
- 1364 • The above also means that chargers and batteries are not integrated into the product
- 1365 and that the product is designed to be easily disassembled.
- 1366 • Strong regulations and monitoring are in place with higher reuse and circular targets,
- 1367 which are set and implemented, and fines are imposed on the member states that fail to
- 1368 achieve the targets.
- 1369 • Support and development of circular strategies infrastructure (e.g., easy information
- 1370 access for repairability, repair shops, accessibility to spare components on the market,
- 1371 etc.).
- 1372 • Greater use of connected products, smart technologies, and the IoT. Used to monitor
- 1373 and diagnose product performance in situ which, can extend product and component
- 1374 life.

#### 1375 **Mining waste (MIN)**

1376 In this scenario, the impact on mining waste is two-fold. Firstly, the need for primary mining  
 1377 is reduced due to efficient resource use and high recovery rates of materials. Secondly, mining  
 1378 waste itself is treated as a valuable resource, with advanced technologies being used to extract  
 1379 residual valuable materials.

- 1380 • A Decrease in primary mining reduces the generation of mining waste.

- 1381 • Advanced technologies are employed to extract valuable materials from mining waste.
- 1382 • Policies and regulations incentivise the reuse of mining waste in various applications.
- 1383 • Digital solutions improve tracking and management of mining waste.
- 1384 • Collaboration between stakeholders promotes circular practices in the mining industry.

#### 1385 **CDW (Construction and Demolition Waste) [eu2008wastedirective]**

1386 Construction and Demolition Waste (CDW) is another sector that sees significant improve-  
1387 ment in the circularity scenario. Emphasising design for disassembly and the use of recyclable  
1388 materials, this scenario drastically reduces the generation of CDW and promotes the recovery  
1389 of valuable materials from the waste stream.

- 1390 • Buildings are designed for disassembly, increasing the lifespan of materials and reducing  
1391 CDW.
- 1392 • Recycling technologies for CDW improve, allowing higher recovery rates of materials.
- 1393 • Policies and regulations incentivise the use of recycled materials in construction.
- 1394 • Standardised systems for CDW collection and separation are established.
- 1395 • Digital tools like building information modelling (BIM) improve resource management in  
1396 construction.
- 1397 • This scenario envisions an almost closed-loop system where CDW is considered a re-  
1398 source, with an emphasis on minimising waste generation and maximising resource  
1399 efficiency in recovery.
- 1400 • Waste reduction is prioritized through the implementation of eco-designs, including  
1401 designing out waste (DOW), lightweight design (LWD), and design for dismantling (DFD).
- 1402 • Reuse and repair standards and networks are established to boost the reuse of end-of-life  
1403 building components and equipment.
- 1404 • If reuse is no longer possible, waste is recycled through high-efficiency recycling facilities  
1405 rather than down-cycled or used for energy recovery.

- 1406 • This scenario is characterized by meeting all material needs through recovery (including  
1407 mineral wastes from other industries) with high material efficiency achieved through the  
1408 development of new business models, advanced designs and recycling technologies,  
1409 strict waste management regulations, and innovative products and services.
- 1410 • Plausible target: Achieving a 100% recovery rate of avoidable CDW by 2050, with a  
1411 recycling rate accounting for 30% and component reuse accounting for 20%. Raw  
1412 material consumption should be reduced by 50% compared to the 2020 level.
- 1413 • Example of treatment technological development: Waste concrete is primarily recy-  
1414 cled through an innovative mobile dry process. Biodiesel-based thermal treatment is  
1415 applied to further pyrolyze the fine aggregate to recover cement. Lightweight design is  
1416 implemented to reduce concrete use.

#### 1417 **SLASH (Slags and Ashes)**

1418 In the circularity scenario, the approach to SLASH dramatically changes. Instead of being  
1419 treated as waste, SLASH is seen as a valuable secondary raw material. Advances in technology  
1420 allow for the extraction of valuable metals and minerals from SLASH, that then re-enter the  
1421 material cycle.

- 1422 • A shift in perception treats SLASH as a valuable resource instead of waste.
- 1423 • Advanced technologies enable the extraction of valuable metals and minerals from  
1424 SLASH.
- 1425 • New regulations incentivise the use of SLASH in various applications, such as in the  
1426 construction industry.
- 1427 • Digital solutions enhance the tracking and management of SLASH.
- 1428 • Collaboration between industries utilises SLASH in new and innovative ways.
- 1429 • Reduce the generation of SLASH by increasing the efficiency of the manufacturing side.  
1430 For example, developing higher efficient production of metals and reducing by-products  
1431 such as smelter slag. For ash from the incineration of solid biomass, maximizing the use

- 1432 of biomass by setting proper temperature, time, and furnace conditions to reduce ash  
1433 contents and improve the efficiency of power and heat generation. For ash, developing  
1434 other renewable technologies from bioenergy to reduce the incineration of solid biomass,  
1435 e.g., biogas.
- 1436 • Reduce the generation of SLASH by increasing the proportion of higher calorific waste  
1437 and decreasing lower calorific waste, e.g., MSW (Municipal Solid Waste).
  - 1438 • Developing domestic feedstock supply for bioenergy or metal production to reduce the  
1439 cost of transportation and others.
  - 1440 • Higher formal collection and recycling rate compared to BAU, but lower compared to  
1441 the Recovery scenario.

## 1442 Chapter 3

# 1443 Quantification

1444

To be completed in the next stages of the project.

## 1451 5.1 Terminology

1452 The following is a suggested terminology for use in our discussions and reports related to  
1453 scenarios.

1454 This glossary is modelled on that used by [skea2021outlooks]. Some additional definitions  
1455 were sourced from [arizona2023].

Table 5.1: Terminology

| Term                     | Definition  | Level/Context        | Also called                       | Source                                     |
|--------------------------|---|----------------------|-----------------------------------|--|
| Normative scenario       | Goal-oriented scenario: identify decisions and investments that must be made to achieve desired future outcomes. Example: Constraining cumulative emissions   | Scenario type        | Backcasting                       | Skea                                       |
| Exploratory scenario     | Exploration of plausible alternative developments to test whether decision-making is robust against different outcomes. Generally, involving a qualitative storyline about a possible future, complemented by quantitative analysis. Example: Socio-economic scenarios  | Scenario type        | Plausible scenarios               | Skea                                       |
| Outlook                  | To provide a most likely estimate of future trends as a guide for decision-making   | Scenario type        | Forecast, projection              | Skea                                       |
| Scenario characteristics | A combination of the vague attributes that make up the qualitative storyline for a scenario. For example, in WEC (2019) the scenario titled Modern Jazz is described as: “A market-led, digitally disrupted world with faster-paced and more uneven economic growth. Recent signals suggest that this entrepreneurial future might accelerate clean energy access on both global and local scales, whilst presenting new systems integration, cyber security and data privacy challenges” | Scenario description | Qualitative storyline descriptors | Skea                                       |
| Scenario scale           | Description of the spatial extent or temporal extent of a scenario. For us, mostly EU toward 2050.  | Scenario component   |                                   | UniArizona                                 |
| Scenario dimensions      | Uncertainties around which scenarios are constructed, represented as axes in some methods. In our case they might end up being, level of circularity, free-trade/autarky, progress in energy transition   | Scenario component   |                                   | UniArizona                                 |
| Scenario literature      | Journal articles, grey literature, etc., from which data is sourced that can be used to justify decisions in scenario development   | Scenario component   |                                   |  |
| Scenario logics          | Methods for structuring the relationships between different drivers and assumptions in scenarios  | Scenario component   |                                   | Rowland et al. 2014 reported in UniArizona |

Continued on next page

Table 5.1 — Continued from previous page

| Term                     | Definition   | Level/Context                 | Also called    | Source   |
|--------------------------|--|-------------------------------|----------------|--|
| Time horizon             | End date of the scenario's forecast  | Scenario attribute            |                | Skea   |
| Snapshot                 | The position of scenario/s at a particular point of time   | Scenario attribute            |                | Skea   |
| Storyline and simulation | Combination of qualitative narrative development and quantitative modelling  | Scenario component            |                | Mahmoud et al. 2009, Wollenberg et al. 2000 reported in UniArizona |
| Marker scenario          | Generally, a widely accepted scenario which can be used a guide or to provide background information. E.g., SSP1-5, and the GEC models from the IEA. If applicable, these can be extended upon or combined to help build our models.   | Scenario description          | Basis scenario | Skea   |
| SSP                      | Shared Social Pathways. They “describe plausible major global developments that together would lead in the future to different challenges for mitigation and adaptation to climate change. The SSPs are based on five narratives describing alternative socio-economic developments, including sustainable development, regional rivalry, inequality, fossil-fuelled development, and middle-of-the-road development. The long-term demographic and economic projections of the SSPs depict a wide uncertainty range consistent with the scenario literature.” | Marker scenario examples      |                | PBL  |
| IEA and GEC              | Global Energy and Climate Model of the International Energy Agency. Used to create their forecasts: Net Zero Emissions (NZE), Announced Pledges Scenario (APS), and Stated Policies Scenario (STEPS)   | Marker scenario examples      |                | IEA  |
| Drivers                  | Underlying causes of system change that are external from the system of analysis. They come from higher scales and are not affected by what happens within the system.   | Scenario component            | Factors        | Walker et al. 2012, reported in UniArizona                         |
| Factors                  | Causes of system change that are internal from the system of analysis. Can be (hopefully) quantified, or at least estimated  | Scenario component (internal) |                |  |

Table 5.1 — Continued from previous page

| Term              | Definition  | Level/Context                   | Also called        | Source                             |
|-------------------|---|---------------------------------|--------------------|------------------------------------|
| Factor variables  | Discrete elements which are subject to change and have effects on one or more factors   | Factor component                |                    |                                    |
| Factor parameters | Discrete elements which are NOT subject to change (possibly based on assumptions and simplifications) and have effects on one or more factors | Factor component                |                    |                                    |
| Trends            | An inclination in a particular direction  | Attribute of drivers or factors | System development |                                    |
| Likelihood        | The likelihood of an occurrence, an outcome, or a result, where this can be estimated probabilistically.                                      | Attribute of drivers or factors | Probability        | Rowland et al. 2014, IPCC standard |
|                   |   |                                 |                    |                                    |

## 1456 **5.2 Scenario development methods**

1457 The following table provides an overview of the methods and tools considered, along with a  
1458 brief description of each and its relevance to the specific context and objectives of the FutuRaM  
1459 scenario development process.

Table 5.2: Scenario development methods

| Method                 | Description   | Key characteristics   | Limitations  | Application   |
|------------------------|---|---|--|---|
| Delphi                 | Structured expert consultation to gather and distil knowledge and judgments       | Iterative rounds of surveys/questionnaires, Expert consensus building                     | Time-consuming process, May be influenced by dominant opinions or group dynamics           | Policy development, Technology foresight, Long-term planning            |
| MCA                    | Decision-support technique to evaluate and rank scenarios based on criteria       | Consideration of multiple dimensions in quantifying qualitative factors                   | Policy assessment, Project evaluation, Strategic planning                                  |   |
| Forecasting            | Use of historical data and statistical methods to predict future trends           | Reliance on quantitative models, Time series analysis                                     | Assumption of future patterns based on past data, Sensitivity to data quality and accuracy | Economic forecasting, Demand/supply projections, Financial planning     |
| Backcasting            | Working backward from a desired future vision to identify necessary steps         | Focus on desired outcomes and future targets, Identification of necessary actions         | Uncertainty in future outcomes, Difficulty in determining feasible pathways                | Sustainable development planning, Policy design, Long-term goal setting |
| Scenario Planning      | Development of multiple future scenarios to understand the range of possibilities | Identification of key drivers and uncertainties, Narrative construction for each scenario | Subjectivity in scenario construction, Lack of predictive accuracy                         | Strategic management, Risk assessment, Policy analysis                  |
| Morphological Analysis | Exploration of different combinations of variables/factors                        | Matrix-based exploration of variables and combinations                                    | Complexity in analysing a large number of variables and combinations                       | Technology assessment, Innovation analysis, System design               |

Continued on next page

Table 5.2 – Continued from previous page

| Method                              | Description   | Key characteristics   | Limitations  | Application   |
|-------------------------------------|---|---|--|---|
| Cross-Impact Analysis               | Analysis of interdependencies and interactions between variables/factors  | Identification of relationships and cross-impacts             | Assumptions about causal relationships, Difficulty in capturing complex dynamics | Policy analysis, Risk assessment, System modelling          |
| Morphological Box                   | Systematic exploration of the potential combinations of different components  | Identification of component options and combinations          | Complexity in analysing a large number of components and combinations            | Technology assessment, Innovation analysis, Decision-making |
| Gausemeier approach                 | Scenario development method involving the identification of future developments, evaluation of influencing factors, and determination of desired and undesired developments   | Systematic analysis of future developments and factors        | Relies on expert judgment and subjective assessments                             | Strategic planning, Innovation management                   |
| Schwartz' 8-Step Scenario Model     | Scenario building model consisting of eight steps: identify the focal issue, determine the key forces, construct the scenario framework, identify driving forces, assess the uncertainties, develop the scenarios, analyze the scenarios, and monitor and adjust the scenarios                  | Systematic progression through stages of scenario development | Requires detailed data and analysis  | Strategic planning, Decision-making                         |
| Schoemaker's 10-Step Scenario Model | Scenario building model consisting of ten steps: identify the focal issue, determine the scope, identify the key driving forces, develop the scenarios, define the scenario logic, assess the scenarios, refine the scenarios, examine implications, formulate actions, and communicate results | Emphasis on thorough analysis and evaluation of scenarios     | Can be time-consuming and resource-intensive                                     | Strategic planning, Risk management                         |
|                                     |   |   |  |   |

### 1460 **5.3 Marker scenario mapping**

1461 The following table presents an overview of the marker scenarios considered in the FutuRaM  
1462 project. The table is not intended to be exhaustive, but rather to provide an overview of the  
1463 different scenarios that have been developed in the field of waste management, resource  
1464 recovery, and circular economy.

Table 5.3: Overview of marker scenarios

| Literature   | Type     | Waste stream     | Temporal Coverage   | Location | Number of scenarios |                      |
|--|----------|------------------|---------------------|----------|---------------------|----------------------|
| The Shared Socioeconomic Pathways and their energy, land use, and greenhouse gas emissions implications: An overview | Academic | All (narratives) | Scenario to 2100    | Global   | 5 SSPs              | <a href="#">Link</a> |
| Environmental Impacts of Global Offshore Wind Energy Development until 2040  | Academic | C&D              | Scenario: 2019–2040 | Global   | 4 (based on IEA)    | <a href="#">Link</a> |
| Global greenhouse gas emissions from residential and commercial building materials and mitigation strategies to 2060 | Academic | C&D              | Scenario: 2020–2060 | Global   | 2 (based on SSP2)   | <a href="#">Link</a> |
| Modelling global material stocks and flows for residential and service sector buildings towards 2050                 | Academic | C&D              | Scenario: 2020–2060 | Global   | 1 (SSP2)            | <a href="#">Link</a> |
| The evolution and future perspectives of energy intensity in the global building sector 1971–2060                    | Academic | C&D              | Scenario: 2020–2060 | Global   | 1 (SSP2)            | <a href="#">Link</a> |

## **5.4 Drivers and factors identified in the initial collection phase**

The following table lists the elements that were identified in the initial phase of driver/factor collection.

Table 5.4: Drivers and factors identified in the initial collection phase

| Method  | Description  |
|---|--|
| Stricter environmental regulations            | Increased regulations and policies aimed at reducing environmental impact    |
| Inflation                                     | Increase in the general price level of goods and services over time          |
| Employment rates                              | Percentage of the working-age population that is employed                    |
| Exchange rates                                | Value of one currency relative to another currency                           |
| Interest rates                                | Cost of borrowing money or the return on investment                          |
| Gasoline price                                | Cost of gasoline for vehicles  |
| Electricity price                             | Cost of electricity for consumers or businesses                              |
| Raw material prices                           | Prices of primary materials used in production processes                     |
| CO2 market                                    | Trading system for carbon emissions permits or credits                       |
| Education level                               | Level of education attained by individuals or the overall population         |
| Volunteering                                  | Engagement in unpaid activities for the benefit of others                    |
| Transparency                                  | Openness, accountability, and information accessibility                      |
| Compliance with rules                         | Adherence to regulations, guidelines, or standards                           |
| Cultural values / Consciousness               | Beliefs, attitudes, and awareness of individuals and society                 |
| Accessibility                                 | Ease of access to goods, services, or infrastructure                         |
| Land rights                                   | Legal rights to ownership, use, or access to land                            |
| Work-life balance                             | Equilibrium between work and personal life                                   |
| Urbanisation                                  | Increase in the population living in urban areas                             |
| Water supply constraints                      | Limitations on the availability or access to freshwater resources            |
| Increased intrinsic drive for env. protection | Growing internal motivation to protect and conserve the environment          |
| NIMBY to projects                             | Not-In-My-Backyard opposition to the location of certain projects            |
| Climate change impacts (flooding, etc.)       | Consequences of climate change, such as increased flooding or extreme events |
| Climate change mitigation efforts             | Actions taken to reduce greenhouse gas emissions and combat climate change   |
| Redundancy                                    | Availability of backup systems or alternative options                        |
| Material efficiency                           | Effective use and management of materials to minimize waste and loss         |
| Energy efficiency of buildings                | Performance and efficiency of energy consumption in buildings                |

Table 5.4 – Continued from previous page

| Driver/factor   | Definition  |
|---|---|
| Change of products in the scope WEEE directive          | Inclusion or exclusion of certain products within the scope of the WEEE directive |
| GDP/PPP   | Gross Domestic Product (GDP) adjusted for purchasing power parity (PPP)           |
| Improved repairability                                  | Enhanced ability to repair and maintain products or equipment                     |
| Target enforcement                                      | Implementation and enforcement of specific targets or goals                       |
| Data protection   | Safeguarding personal data and ensuring privacy                                   |
| Infrastructure  | Physical structures and facilities necessary for the functioning of society       |
| Intellectual property issues                            | Legal rights and protections for intellectual creations and innovations           |
| Population  | Total number of people in a given area or region                                  |
| Resource shortage                                       | Insufficient availability or scarcity of natural resources                        |
| Treatment cost  | Cost of waste treatment, disposal, or recycling processes                         |
| Digital product passports                               | Digital documentation providing information about a product's lifecycle           |
| Obsolescence  | State of being outdated or no longer in use or demand                             |
| Digitalization  | Integration and adoption of digital technologies and processes                    |
| SRM prices  | Prices of secondary raw materials or recycled materials                           |
| Product prices  | Prices of goods or products in the market   |
| Recyclability mandates                                  | Requirements or regulations promoting the recyclability of products               |
| Conflict in supply chain                                | Disputes or conflicts within the supply chain of raw materials or products        |
| Obligatory recycling standards for treatment facilities | Mandatory standards for recycling processes in treatment facilities               |
| Improved durability                                     | Enhanced longevity and resistance of products or materials                        |
| Composition change                                      | Alteration or modification of the composition of materials or products            |
| Subsidies   | Financial support or incentives provided by governments or organizations          |
| Availability of recovery technologies                   | Existence and accessibility of technologies for material recovery                 |
| Taxation (raw materials, landfill)                      | Imposition of taxes on raw materials or landfill activities                       |
| Obligatory removal of CRMs from waste                   | Required removal or extraction of critical raw materials from waste streams       |
| Corruption  | Dishonest or unethical behaviour, typically involving misuse of power             |
| Supply chain due diligence laws                         | Regulations or laws requiring companies to assess and manage supply chain risks   |

Table 5.4 – Continued from previous page

| Driver/factor                   | Definition   |
|---------------------------------|--|
| Improved recyclability          | Increased ability of products or materials to be recycled or reused        |
| Ecodesign                       | Designing products with consideration for their environmental impact       |
| Trade barriers                  | Barriers or restrictions to international trade or commerce                |
| Industrialization of Europe     | Development and growth of industrial activities in European countries      |
| Reduced consumerism             | Shift towards decreased consumption and a more sustainable lifestyle       |
| Accessibility/Infrastructure    | Availability and adequacy of infrastructure to support accessibility       |
| New mines in rich EU countries? | Establishment of new mines in economically prosperous European countries   |
| Miniaturization                 | Process of making products or components smaller and more compact          |
| Sharing economy                 | Economic system based on sharing resources and services                    |
| Repairability mandates          | Requirements or regulations promoting the repairability of products        |
| Renewable energy targets        | Set goals or objectives for increasing the use of renewable energy sources |
|                                 |  |

## 1468 **5.5 Drivers and factors identified in the screening phase**

1469 The following table lists the scenario elements that were identified in the screening phase of  
1470 driver/factor collection.

Table 5.5: List of drivers and factors identified in the screening phase

| Domain          | Driver/factor                                      | Definition   | BAU | REC | CIR |
|-----------------|--|--|-----|-----|-----|
| Economic        | CO2 market price                                   | Price of carbon dioxide (CO2) emissions in carbon markets  | I   | I   | I   |
| Economic        | Economic growth                                    | Rate of economic growth  | I   | I   | I   |
| Economic        | Energy prices                                      | Prices of energy resources   | I   | I   | I   |
| Economic        | Market saturation                                  | Level of saturation reached in the market for certain products or services   | I   | I   | II  |
| Economic        | Raw material vs SRM prices                         | Price comparison between raw materials and Secondary Raw Materials (SRMs)  | I   | I   | I   |
| Economic        | Re-industrialisation of EU                         | Process of revitalizing industrial activities in the European Union  | I   | I   | I   |
| Environmental   | Climate change impacts (flooding, etc.)            | Impacts of climate change such as flooding and other related events  | I   | I   | I   |
| Environmental   | Climate change mitigation efforts                  | Efforts made to mitigate the effects of climate change   | I   | I   | I   |
| Environmental   | Increased drive for env. protection                | Growing motivation and drive to protect the environment  | I   | III | III |
| Environmental   | Resource shortage                                  | Shortage of natural resources  | I   | I   | I   |
| Legal/Political | Ecodesign/re-X mandates                            | Establishment of ecodesign requirements for specific product groups to improve circularity, energy performance, and other environmental sustainability aspects | I   | II  | III |
| Legal/Political | Governance: corruption vs compliance               | Contrasting levels of corruption and compliance within governance systems  | I   | I   | I   |
| Legal/Political | International trade and co-operation (vs. autarky) | Level of international trade and cooperation versus self-sufficiency   | I   | I   | I   |
| Legal/Political | Product information transparency                   | Provision of transparent product information to consumers, manufacturers, importers, repairers, recyclers, or national authorities                             | I   | III | III |
| Legal/Political | Progress toward renewable energy targets           | Progress made in achieving renewable energy targets  | I   | I   | I   |
| Legal/Political | Stricter environmental regulations                 | Implementation of more stringent rules and regulations for environmental protection  | I   | III | III |
| Legal/Political | Subsidies/taxation to promote circularity          | Provision of subsidies or implementation of taxation policies to incentivize circularity   | I   | I   | I   |
| Legal/Political | Supply chain due diligence laws                    | Implementation and enforcement of laws requiring companies to address negative human rights and environmental impacts in their value chains                    | I   | II  | III |
| Social          | Hoarding   | The act of stockpiling and keeping excessive amounts of products   | III | II  | II  |

Table 5.5 — Continued from previous page

| Domain    | Driver/factor                       | Definition   | BAU | REC | CIR |
|-----------|-------------------------------------|--|-----|-----|-----|
| Social    | NIMBY to projects                   | Opposition of local communities to the location of new projects, such as mining, in their vicinity                         | I   | I   | I   |
| Social    | Participation in re-X activities    | "Involvement in activities related to the ""re-"" concepts, including refusing, reducing, repairing, and reusing products" | I   | II  | III |
| Social    | Population                          | Size and growth of the population  | I   | I   | I   |
| Social    | Urbanisation                        | Rate of urban population growth  | I   | I   | I   |
| Technical | Digitisation                        | Adoption and integration of digital technologies   | I   | I   | I   |
| Technical | Integration of SRM system across EU | Integration of a Secondary Raw Materials (SRM) system across the European Union  | I   | III | III |
| Technical | Product technology                  | Changes in product function or composition that lead to changes in waste stream composition and quantity                   | I   | III | III |
| Technical | Recovery technology                 | Technologies and processes for recovering materials from waste   | I   | III | III |
|           |                                     |  |     |     |     |
